Gmedian-package

Geometric Median, k-Medians Clustering and Robust Median PCA

Description

The geometric median (also called spatial median or L1 median) is a robust multivariate indicator of central position. This library provides fast estimation procedures that can handle rapidly large samples of high dimensional data. Function Gmedian computes the geometric median of a numerical data set with averaged stochastic gradient algorithms, whereas GmedianCov computes the median covariation matrix, a useful indicator for robust PCA. Robust clustering, based on the geometric k-medians, can also be performed with the same type of recursive algorithm thanks to kGmedian. Less fast estimation procedures based on Weiszfeld's algorithm are also available: function Weiszfeld computes the geometric median whereas WeiszfeldCov computes the median covariation matrix. These procedures may be preferred for small and moderate sample sizes. Note that weighting statistical units (for example with survey sampling weights) is allowed.

Gmedian Gmedian

Description

Computes recursively the Geometric median (also named spatial median or L1-median) with a fast averaged stochastic gradient algorithms that can deal rapidly with large samples of high dimensional data.

Usage

```
Gmedian(X, init = NULL, gamma = 2, alpha = 0.75, nstart=2, epsilon=1e-08)
```

Arguments

Χ	Data matrix, with n (rows) observations in dimension d (columns).
init	When NULL the starting point of the algorithm is the first observation. Else the starting point of the algorithm is provided by init.
gamma	Value (positive) of the constant controling the descent steps (see details).
alpha	Rate of decrease of the descent steps (see details). Should satisfy $1/2 < alpha <= 1$.
nstart	Number of times the algorithm is ran over all the data set.
epsilon	Numerical tolerance. By defaut set to 1e-08.

Details

The recursive averaged algorithm is described in Cardot, Cenac, Zitt (2013), with descent steps defined as $\alpha_n = gamma/n^{alpha}$.

4 Gmedian

Value

Vector of the geometric median.

References

Cardot, H., Cenac, P. and Zitt, P-A. (2013). Efficient and fast estimation of the geometric median in Hilbert spaces with an averaged stochastic gradient algorithm. *Bernoulli*, 19, 18-43.

Examples

```
## Simulated data - Brownian paths
n <- 1e2
d <- 100
x <- matrix(rnorm(n*d,sd=1/sqrt(d)), n, d)</pre>
x \leftarrow t(apply(x,1,cumsum))
## Computation speed
system.time(replicate(10, {
  median.est = Gmedian(x)}))
system.time(replicate(10, {
  mean.est = apply(x,2,mean)))
##
## Accuracy with contaminated data
n <- 1e03
d <- 10
n.contaminated <- 0.05*n ## 5% of contaminated observations
n.experiment <- 100
err.L2 <- matrix(NA,ncol=3,nrow=n.experiment)</pre>
colnames(err.L2) = c("mean (no contam.)", "mean (contam.)", "Gmedian")
for (n.sim in 1:n.experiment){
x <- matrix(rnorm(n*d,sd=1/sqrt(d)), n, d)</pre>
x \leftarrow t(apply(x,1,cumsum))
err.L2[n.sim,1] \leftarrow sum((apply(x,2,mean))^2/d)
ind.contaminated <- sample(1:n,n.contaminated) ## contam. units</pre>
x[ind.contaminated,] <- 5
err.L2[n.sim, 2] \leftarrow sum((apply(x, 2, mean))^2/d)
err.L2[n.sim,3] \leftarrow sum(Gmedian(x)^2/d)
boxplot(err.L2,main="L2 error")
```

GmedianCov 5

GmedianCov GmedianCov

Description

Computes recursively the Geometric median and the (geometric) median covariation matrix with fast averaged stochastic gradient algorithms. The estimation of the Geometric median is performed first and then the median covariation matrix is estimated, as well as its leading eigenvectors. The original recursive estimator of the median covariation matrix may not be a non negative matrix. A fast projected estimator onto the convex closed cone of the non negative matrices allows to get a non negative solution.

Usage

```
GmedianCov(X, init=NULL, nn=TRUE, scores=2, gamma=2, gc=2, alpha=0.75, nstart=1)
```

Arguments

when NULL the starting point of the algorithm estimating the median is the first observation. When TRUE the algorithm provides a non negative estimates of the median covariation matrix. When nn=FALSE, the original algorithm is performed, with no guaranty that all the eigenvalues of the estimates are non negative An integer q, by default q=2. The function computes the eigenvectors of the median covariation matrix associated to the q largest eigenvalues and the corresponding principal component scores. No output if scores=0. By alma algorithm computing median. By algorithm computing median. By alue (positive) of the constant controling the descent steps (see details) for algorithm computing the median covariation matrix By alpha algorithm computing the descent steps (see details) for algorithm computing the median covariation matrix By alpha algorithm conformation the descent steps (see details) for algorithm computing the median covariation matrix By alpha algorithm computing the descent steps (see details) for algorithm computing the median covariation matrix By alpha algorithm conformation the descent steps (see details) for algorithm computing the median covariation matrix	Χ	Data matrix, with n observations (rows) in dimension d (columns).
variation matrix. When nn=FALSE, the original algorithm is performed, with no guaranty that all the eigenvalues of the estimates are non negative scores An integer q, by default q=2. The function computes the eigenvectors of the median covariation matrix associated to the q largest eigenvalues and the corresponding principal component scores. No output if scores=0. yalue (positive) of the constant controling the descent steps (see details) for the algorithm computing median. yalue (positive) of the constant controling the descent steps (see details) for algorithm computing the median covariation matrix alpha Rate of decrease of the descent steps, 1/2 < alpha <= 1.	init

	gc	
nstart Number of time the algorithms are ran.	alpha	Rate of decrease of the descent steps, $1/2 < alpha <= 1$.
	nstart	Number of time the algorithms are ran.

Details

The (fast) computation of the eigenvectors is performed by eigs_sym of package RSpectra. See Cardot, H. and Godichon-Baggioni (2017) for more details on the recursive algorithm. See also Gmedian. When nn=TRUE, the descent step is bounded above so that the solution remains non negative at each iteration. The principal components standard deviation is estimed robustly thanks to function scaleTau2 from package robustbase.

6 kGmedian

Value

median Vector of the geometric median

covmedian Median covariation matrix

vectors The scores=q eigenvectors of the median covariation matrix associated to the q
largest eigenvalues

scores Principal component scores corresponding to the scores=q eigenvectors

The scores=q estimates of the standard deviation of the scores=q principal
components.

lines(c(1:d)/d,median.est$vectors[,2]*sqrt(d),lty=2)</pre>
```

kGmedian *kGmedian*

Description

Fast k-medians clustering based on recursive averaged stochastic gradient algorithms. The procedure is similar to the kmeans clustering technique performed recursively with the MacQueen algorithm. The advantage of the kGmedian algorithm compared to MacQueen strategy is that it deals with sum of norms instead of sum of squared norms, ensuring a more robust behaviour against outlying values.

kGmedian 7

Usage

```
kGmedian(X, ncenters=2, gamma=1, alpha=0.75, nstart = 10, nstartkmeans = 10, iter.max = 20)
```

Arguments

X matrix, with n observations (rows) in dimension d (columns).

ncenters Either the number of clusters, say k, or a set of initial (distinct) cluster centres.

If a number, the initial centres are chosen as the output of the kmeans function

computed with the MacQueen algorithm.

gamma Value of the constant controlling the descent steps (see details).

alpha Rate of decrease of the descent steps.

nstart Number of times the algorithm is ran, with random sets of initialization centers

chosen among the observations.

nstartkmeans Number of initialization points in the kmeans function for choosing the starting

point of kGmedian.

iter.max Maximum number of iterations considered in the kmeans function for choosing

the starting point of kGmedian.

Details

See Cardot, Cenac and Monnez (2012).

Value

cluster A vector of integers (from 1:k) indicating the cluster to which each point is

allocated.

centers A matrix of cluster centres.

withinsrs Vector of within-cluster sum of norms, one component per cluster.

size The number of points in each cluster.

8 Weiszfeld

Examples

Weiszfeld

Weiszfeld

Description

Computes the Geometric median (also named spatial median or L1-median) with Weiszfeld's algorithm.

Usage

```
Weiszfeld(X, weights = NULL, epsilon=1e-08, nitermax = 100)
```

Arguments

X	Data matrix, with n (rows) observations in dimension d (columns).
weights	When NULL, all observations have the same weight, say 1/n. Else, the user can provide a size n vector of weights (such as sampling weights). These weights are used in the estimating equation (see details).
epsilon	Numerical tolerance. By defaut 1e-08.
nitermax	Maximum number of iterations of the algorithm. By default set to 100.

Details

Weizfeld's algorithm (see Vardi and Zhang, 2000) is fast and accurate and can deal with large samples of high dimension data. However it is not as fast as the recursive approach proposed in Gmedian, which may be preferred for very large samples in high dimension. Weights can be given for statistical units, allowing to deal with data drawn from unequal probability sampling designs (see Lardin-Puech, Cardot and Goga, 2014).

Weiszfeld 9

Value

median Vector of the geometric median.

iter Number of iterations

```
## Robustness of the geometric median of n=3 points in dimension d=2.
a1 <- c(-1,0); a2 <- c(1,0); a3 <-c(0,1)
data.mat <- rbind(a1,a2,a3)</pre>
plot(data.mat,xlab="x",ylab="y")
med.est <- Weiszfeld(data.mat)</pre>
points(med.est$median,pch=19)
 ### weighted units
poids = c(3/2,1,1)
plot(data.mat,xlab="x",ylab="y")
med.est <- Weiszfeld(data.mat,weights=poids)</pre>
plot(data.mat,xlab="x",ylab="y")
points(med.est$median,pch=19)
## outlier
data.mat[3,] <- c(0,10)
plot(data.mat,xlab="x",ylab="y")
med.est <- Weiszfeld(data.mat)</pre>
points(med.est$median,pch=19)
## Computation speed
## Simulated data - Brownian paths
n \leftarrow 1e2 \ \text{\#\# choose} \ n \leftarrow 1e5 \ \text{for better evaluation}
x <- matrix(rnorm(n*d,sd=1/sqrt(d)), n, d)</pre>
x \leftarrow t(apply(x,1,cumsum))
system.time(replicate(10, {
  median.est = Weiszfeld(x)}))
system.time(replicate(10, {
  median.est = Gmedian(x)))
system.time(replicate(10, {
  mean.est = apply(x,2,mean)))
```

10 WeiszfeldCov

	WeiszfeldCov	WeiszfeldCov
--	--------------	--------------

Description

Estimation of the Geometric median covariation matrix with Weiszfeld's algorithm. Weights (such as sampling weights) for statistical units are allowed.

Usage

```
WeiszfeldCov(X, weights=NULL, scores=2, epsilon=1e-08, nitermax = 100)
```

Arguments

Χ	Data matrix, with n (rows) observations in dimension d (columns).
weights	When NULL, all observations have the same weight, say 1/n. Else, the user can provide a size n vector of weights (such as sampling weights). These weights are used in the estimating equation (see details).
scores	An integer q, by default q=2. The function computes the eigenvectors of the median covariation matrix associated to the q largest eigenvalues and the corresponding principal component scores. No output if scores=0.
epsilon	Numerical tolerance. By defaut 1e-08.
nitermax	Maxium number of iterations of the algorithm. By default set to 100.

Details

This fast and accurate iterative algorithm can deal with moderate size datasets. For large datasets use preferably GmedianCov, if fast estimations are required. Weights can be given for statistical units, allowing to deal with data drawn from unequal probability sampling designs (see Lardin-Puech, Cardot and Goga, 2014). The principal components standard deviation is estimed robustly thanks to function scaleTau2 from package robustbase.

Value

median	Vector of the geometric median
covmedian	Median covariation matrix
vectors	The scores=q eigenvectors of the median covariation matrix associated to the q largest eigenvalues
scores	Principal component scores corresponding to the scores=q eigenvectors
sdev	The scores=q robust estimates of the standard deviation of the principal components scores
iterm	Number of iterations needed to estimate the median
itercov	Number of iterations needed to estimate the median covariation matrix.
