Title Utility Functions for Exploratory Factor Analysis

Version 2.1.3
Author Guangjian Zhang, Ge Jiang, Minami Hattori, Lauren Trichtinger
Maintainer Guangjian Zhang <gzhang3@nd.edu></gzhang3@nd.edu>
<b>Depends</b> R (>= 2.10)
<b>Description</b> A number of utility function for exploratory factor analysis are included in this package. In particular, it computes standard errors for parameter estimates and factor correlations under a variety of conditions.
License GPL-2

Align.Matrix BFI228 CPAI537 efa

2 Align.Matrix

|--|--|

## **Description**

The function is to align a factor solution according to an order matrix. The output matrix is a (p+m+1) by m matrix, where the first p rows are factor loadings of the best match, the next m rows are factor correlations of the best match, and the last row contains the sums of squared deviations for the best match and the second best match. The difference between the best match and the second best match could be considered as a confidence on the success of the aligning procedure (a computationally more efficient method exists for some conditions; whenever this occurs we only report that of the best match).

## Usage

```
Align.Matrix(Order.Matrix, Input.Matrix, Weight.Matrix=NULL)
```

#### **Arguments**

Order.Matrix	A p by m matrix: p is the number of manifest variables and m is the number of latent factors
Input.Matrix	A (p+m) by m matrix, the first p rows are factor loadings, the last m rows are factor correlations
Weight.Matrix	A p by m matrix that assigns weight to the order matrix: NULL (default)

## **Details**

Align.Matrix is an R function to reflect and interchange columns of Input.Matrix to match those of Order.Matrix. Because it considers all possible permutations of columns of Input.Matrix,the best match in terms of the smallest sum of squared deviations between these two matrices can always be found. It may be slow if there are too many factors.

## Author(s)

Guangjian Zhang

## **Examples**

```
#Order Matrix
A <- matrix(c(0.8,0.7,0,0,0,0,0.8,0.7),nrow=4,ncol=2)
#Input.Matrix
B <-matrix(c(0,0,-0.8,-0.7,1,-0.2,0.8,0.7,0,0,-0.2,1),nrow=6,ncol=2)
Align.Matrix(Order.Matrix=A, Input.Matrix=B)</pre>
```

BFI228 3

BFI228

Ordinal Data of the Big Five Inventory (BFI)

## **Description**

The BFI228 is part of the study on personality and relationship satisfaction (Luo, 2005). The participants were 228 undergraduate students at a large public university in the US. The data were participants' self ratings on the 44 items of the Big Five Inventory (John, Donahue, & Kentle, 1991). These items are Likert variables: disagree strongly (1), disagree a little (2), neither agree nor disagree (3), agree a little (4), and agree strongly (5).

## Usage

data(BFI228)

#### **Format**

The format is a n by p matrix of ordinal variables, where n is the number of participants (228) and p is the number of manifest variables (44).

## **Details**

The variables were ordered such that indicators of the same factor are grouped together. Note that reverse-coded items are denoted by 'R'.

V01 to V08 are variables for the factor extraversion: talkative, reserved\_R, fullenergy, enthusiastic, quiet\_R, assertive, shy\_R, and outgoing.

V09 to V17 are variables for the factor agreeableness: findfault\_R, helpful, quarrels\_R, forgiving, trusting, cold\_R, considerate, rude\_R, and cooperative.

V18 to V26 are variables for the factor conscientiousness are: thorough, careless\_R, reliable, disorganized\_R, lazy\_R, persevere, efficient, plans, and distracted\_R.

V27 to V34 are variables for the factor neuroticism: blue, relaxed\_R, tense, worries, emostable\_R, moody, calm\_R, and nervous.

V35 to V44 are variables for the factor openness: ideas, curious, ingenious, imagination, inventive, artistic, routine\_R, reflect, nonartistic, and sophisticated.

4 CPAI537

CPAI537

Composite Scores of the Chinese Personality Assessment Inventory (CPAI)

## **Description**

CPAI537 is part of a big survey study on martial satisfaction (Luo et al., 2008). The participants were 537 urban Chinese couples in the first year of their marriage. Included here are 28 composite scores of the CPAI (Cheung et al., 1996) for the 537 wives.

## Usage

data(CPAI537)

#### **Format**

The format is a n by p matrix, where n is the number of participants (537) and p is the number of manifest variables (28).

#### Details

The column names stand for the following variable names:

Nov - Novelty

Div - Diversity

Dit - Diverse thinking

LEA - Leadership

L\_A - Logical orientation vs affective orientation

AES - Aesthetics

E\_I - Extroversion-Introversion

ENT - Enterprise

RES - Responsibility

EMO - Emotionality

I\_S - Inferiority vs. self-acceptance

PRA - Practical mindedness

O\_P - Optimistic vs. pessimistic

MET - Meticulousness

FAC - Face

I\_E - Internal control vs. external control

FAM - Family orientation

DEF - Defensiveness

G\_M - Graciousness vs. meanness

INT - Interpersonal tolerance

S\_S - Self orientation vs. social orientation

V S - Veraciousness vs. slickness

T\_M - Traditionalism vs. modernity

REN - Relationship orientation

SOC - Social sensitivity

```
DIS - Discipline
HAR - Harmony
T_E - Thrift vs. extravagance
```

efa

Exploratory Factor Analysis

## **Description**

Performs exploratory factor analysis under a variety of conditions. In particular, it provides standard errors for rotated factor loadings and factor correlations for normal variables, nonnormal continuous variables, and Likert scale variables with and without model error.

## Usage

```
efa(x=NULL, factors=NULL, covmat=NULL, acm=NULL, n.obs=NULL, dist='normal',
fm='ols', mtest = TRUE, rtype='oblique', rotation='CF-varimax', normalize=FALSE,
maxit=1000, geomin.delta=NULL, MTarget=NULL, MWeight=NULL, PhiWeight = NULL,
PhiTarget = NULL, useorder=FALSE, se='sandwich', LConfid=c(0.95,0.90),
CItype='pse', Ib=2000, mnames=NULL, fnames=NULL, merror='YES', wxt2 = 1e0,
I.cr=NULL, PowerParam = c(0.05,0.3))
```

## **Arguments**

X	The raw data: an n-by-p matrix where n is number of participants and p is the number of manifest variables.
factors	The number of factors m: specified by the researcher; the default one is the Kaiser rule which is the number of eigenvalues of covmat larger than one.
covmat	A p-by-p manifest variable correlation matrix.
acm	A $p(p-1)/2$ by $p(p-1)/2$ asymptotic covariance matrix of correlations: specified by the researcher.
n.obs	The number of participants used in calculating the correlation matrix. This is not required when the raw data (x) is provided.
dist	Manifest variable distributions: 'normal'(default), 'continuous', 'ordinal' and 'ts'. 'normal' stands for normal distribution. 'continuous' stands for nonnormal continuous distributions. 'ordinal' stands for Likert scale variable. 'ts' stands for distributions for time-series data.

fm Factor extraction methods: 'ols' (default) and 'ml'
mtest Whether the test statistic is computed: TRUE (default) and FALSE

rtype Factor rotation types: 'oblique' (default) and 'orthogonal'. Factors are corre-

lated in 'oblique' rotation, and they are uncorrelated in 'orthogonal' rotation.

rotation Factor rotation criteria: 'CF-varimax' (default), 'CF-quartimax', 'CF-equamax',

'CF-facparsim', 'CF-parsimax', 'target', and 'geomin'. These rotation criteria can be used in both orthogonal and oblique rotation. In addition, a fifth rotation criterion 'xtarget' (extended target) rotation is available for oblique rotation. The extended target rotation allows targets to be specified on both factor loadings and

factor correlations.

normalize Row standardization in factor rotation: FALSE (default) and TRUE (Kaiser stan-

dardization).

maxit Maximum number of iterations in factor rotation: 1000 (default)

geomin.delta The controlling parameter in Geomin rotation, 0.01 as the default value.

MTarget The p-by-m target matrix for the factor loading matrix in target rotation and

xtarget rotation.

MWeight The p-by-m weight matrix for the factor loading matrix in target rotation and

xtarget rotation. Optional

PhiWeight The m-by-m target matrix for the factor correlation matrix in xtarget rotation.

**Optional** 

PhiTarget The m-by-m weight matrix for the factor correlation matrix in xtarget rotation

useorder Whether an order matrix is used for factor alignment: FALSE (default) and

TRUE

se Methods for estimating standard errors for rotated factor loadings and factor

correlations, 'information', 'sandwich', 'bootstrap', and 'jackknife'. For normal variables and ml estimation, the default method is 'information'. For all other situations, the default method is 'sandwich'. In addition, the 'bootstrap' and

'jackknife' methods require raw data.

LConfid Confidence levels for model parameters (factor loadings and factor correlations)

and RMSEA, respectively: c(.95, .90) as default.

CItype Type of confidence intervals: 'pse' (default) or 'percentile'. CIs with 'pse' are

based on point and standard error estimates; CIs with 'percentile' are based on

bootstrap percentiles.

The number of bootstrap samples when se='bootstrap': 2000 (default)

mnames Names of p manifest variables: Null (default)

fnames Names of m factors: Null (default)

merror Model error: 'YES' (default) or 'NO'. In general, we expect our model is a

parsimonious representation to the complex real world. Thus, some amount of model error is unavailable. When merror = 'NO', the efa model is assumed to

fit perfectly in the population.

wxt2 The relative weight for factor correlations in 'xtarget' (extended target) rotation:

1 (default)

I.cr a n.cr-by-2 matrix for specifying correlated residuals: each row corresponds to

such a residual, the two columns specify the row and the column of the residual.

PowerParam Power analysis related parameters: (0.05, 0.30) as default. The alpha level of

the tests is 0.05, and a salient loading is at least 0.30.

#### **Details**

The function efa conducts exploratory factor analysis (EFA) (Gorsuch, 1983) in a variety of conditions. Data can be normal variables, non-normal continuous variables, and Likert variables. Our implementation of EFA includes three major steps: factor extraction, factor rotation, and estimating standard errors for rotated factor loadings and factor correlations.

Factors can be extracted using two methods: maximum likelihood estimation (ml) and ordinary least squares (ols). These factor loading matrices are referred to as unrotated factor loading matrices. The ml unrotated factor loading matrix is obtained using factanal. The ols unrotated factor loading matrix is obtained using optim where the residual sum of squares is minimized. The starting values for communalities are squared multiple correlations (SMCs). The test statistic and model fit measures are provided.

Seven rotation criteria (CF-varimax, CF-quartimax, 'CF-equamax', 'CF-facparsim', 'CF-parsimax', geomin, and target) are available for both orthogonal rotation and oblique rotation (Browne, 2001). Additionally, a new rotation criteria, xtarget, can be specified for oblique rotation. The factor rotation methods are achieved by calling functions in the package GPArotation. CF-varimax, CFquartimax, CF-equamax, CF-facparsim, and CF-parsimax are members of the Crawford-Fugersion family (Crawford, & Ferguson, 1970) whose kappa is 1/p, 0, m/2p, 1, and (m-1)/(p+m-2) respectively where p is the number of manifest variables and m is the number of factors. CF-varimax and CF-quartimax are equivalent to varimax and quartimax rotation in orthogonal rotation. The equivalence does not carry over to oblique rotation, however. Although varimax and quartimax often fail to give satisfactory results in oblique rotation, CF-varimax and CF-quartimax do give satisfactory results in many oblique rotation applications. CF-quartimax rotation is equivalent to direct oblimin rotation for oblique rotation. The target matrix in target rotation can either be a fully specified matrix or a partially specified matrix. Target rotation can be considered as a procedure which is located between EFA and CFA. In CFA, if a factor loading is specified to be zero, its value is fixed to be zero; if target rotation, if a factor loading is specified to be zero, it is made to zero as close as possible. In xtarget rotation, target values can be specified on both factor loadings and factor correlations.

Confidence intervals for rotated factor loadings and correlation matrices are constructed using point estimates and their standard error estimates. Standard errors for rotated factor loadings and factor correlations are computed using a sandwich method (Ogasawara, 1998; Yuan, Marshall, & Bentler, 2002), which generalizes the augmented information method (Jennrich, 1974). The sandwich standard error are consistent estimates even when the data distribution is non-normal and model error exists in the population. Sandwich standard error estimates require a consistent estimate of the asymptotic covariance matrix of manifest variable correlations. Such estimates are described in Browne & Shapiro (1986) for non-normal continuous variables and in Yuan & Schuster (2013) for Likert variables. Estimation of the asymptotic covariance matrix of polychoric correlations is slow if the EFA model involves a large number of Likert variables.

When manifest variables are normally distributed (dist = 'normal') and model error does not exist (merror = 'NO'), the sandwich standard errors are equivalent to the usual standard error estimates, which come from the inverse of the information matrix. The information standard error

estimates in EFA is available CEFA (Browne, Cudeck, Tateneni, & Mels, 2010) and SAS Proc Factor. Mplus (Muthen & Muthen, 2015) also implemented a version of sandwich standard errors for EFA, which are robust against non-normal distribution but not model error. Sandwich standard errors computed in efa tend to be larger than those computed in Mplus. Sandwich standard errors for non-normal distributions and with model error are equivalent to the infinitesimal jackknife standard errors described in Zhang, Preacher, & Jennrich (2012). Two computationally intensive standard error methods (se='bootstrap' and se='jackknife') are also implemented. More details on standard error estimation methods in EFA are documented in Zhang (2014).

#### Value

An object of class efa, which includes:

details summary information about the analysis such as number of manifest variables,

number of factors, sample size, factor extraction method, factor rotation method, target values for target rotation and xtarget rotation, and levels for confidence

intervals.

unrotated the unrotated factor loading matrix

fdiscrepancy discrepancy function value used in factor extraction

convergence whether the factor extraction stage converged successfully, successful conver-

gence indicated by 0

heywood the number of heywood cases

i.boundary.cr the number of boundary estimates of residual correlations

ng the number of model parameters

compsi Eigenvalues, SMCs (starting values for communality), communality, and unique

variance

R0 the sample correlation matrix

Phat the model implied correlation matrix

Psi Unique variances (and Residual Correlations)

Residual the residual correlation matrix rotated the rotated factor loadings

Phi the rotated factor correlations

rotatedse the standard errors for rotated factor loadings

Phise the standard errors for rotated factor correlations

Psise the standard errors for Unique variances (and Residual Correlations)

ModelF the test statistic and measures of model fit

rotatedlow the lower bound of confidence levels for factor loadings
rotatedupper the upper bound of confidence levels for factor loadings
the lower bound of confidence levels for factor correlations
Phiupper the lower bound of confidence levels for factor correlations

Psilow the lower bound of confidence levels for unique variances (and residual correla-

tions)

Psiupper	the upper bound of confidence levels for unique variances (and residual correlations)
N0Lambda	The required sample sizes for signficant factor loadings (H0: lambda=0)
N1Lambda	The required sample sizes for signficant factor loadings (H0: lambda=Salient)
N0Phi	The required sample sizes for signficant factor correlations (H0: rho=0)
N1Phi	The required sample sizes for signficant factor correlations (H0: rho=salient)

Exploratory Factor Analysis with Multiple Rotations

## **Description**

The function compares EFA solutions from multiple random starts or from multiple rotation criteria.

## Usage

## **Arguments**

X	The raw data: an n-by-p matrix where n is number of participants and p is the number of manifest variables.
factors	The number of factors m: specified by a researcher; the default one is the Kaiser rule which is the number of eigenvalues of covmat larger than one.
covmat	A p-by-p manifest variable correlation matrix.
n.obs	The number of participants used in calculating the correlation matrix. This is not required when the raw data $(x)$ is provided.
dist	Manifest variable distributions: 'normal'(default), 'continuous', 'ordinal' and 'ts'. 'normal' stands for normal distribution. 'continuous' stands for nonnormal continuous distributions. 'ordinal' stands for Likert scale variable. "ts" stands for distributions for time-series data.
fm	Factor extraction methods: 'ols' (default) and 'ml'
rtype	Factor rotation types: 'oblique' (default) and 'orthogonal'. Factors are correlated in 'oblique' rotation, and they are uncorrelated in 'orthogonal' rotation.
rotation	Factor rotation criteria: 'CF-varimax' (default), 'CF-quartimax', 'CF-equamax', 'CF-facparsim', 'CF-parsimax', 'target', and 'geomin'. These rotation criteria can be used in both orthogonal and oblique rotation. In addition, a fifth rotation criterion 'xtarget' (extended target) rotation is available for oblique rotation. The

efaMR 13

extended target rotation allows targets to be specified on both factor loadings and factor correlations. A p-by-m unrotated factor loading matrix. It can replace x or covmat as input input.A arguments. Only factor rotation will be conducted; factor extraction will not be conducted. A string of factor extraction methods against which the main rotation is comadditionalRC pared. Required only when nstart = 1. See details. nstart The number random orthogonal starts used, with 100 as the default value. With nstart = 1, only one random start is used. See details. 'First' (default) or 'All': The global solution is compared against all local solucompare tions with 'First'; All solutions are compared with each other with 'All'. Whether a bar graph that shows the number and frequencies of local solutions plot or not: TRUE (default) and FALSE. A tuning parameter if the plot is produced: .5 (default) cex normalize Row standardization in factor rotation: FALSE (default) and TRUE (Kaiser standardization). geomin.delta The controlling parameter in Geomin rotation, 0.01 as the default value. The p-by-m target matrix for the factor loading matrix in target rotation or xtar-MTarget get rotation. MWeight The p-by-m weight matrix for the factor loading matrix in target rotation or xtarget rotation. The m-by-m target matrix for the factor correlation matrix in xtarget rotation. PhiTarget PhiWeight The m-by-m weight matrix for the factor correlation matrix in xtarget rotation. useorder Whether an order matrix is used for factor alignment: FALSE (default) and **TRUE** mnames Names of p manifest variables: Null (default)

fnames Names of m factors: Null (default)

wxt2 The relative weight for factor correlations in 'xtarget' (extended target) rotation:

1 (default)

#### **Details**

efaMR performs EFA with multiple rotation using random starts.

Geomin rotation, in particular, is known to produce multiple local solutions; the use of random starts is advised (Hattori, Zhang, & Preacher, 2018).

The p-by-m unrotated factor loading matrix is post-multiplied by an m-by-m random orthogonal matrices before rotation.

The number of random starts can be specified with the default value of nstart = 100. Bar plot that represents frequencies of each solution is provided. If multiple solutions are found, they are compared with each other using congruence coefficient.

If nstart = 1, no random start is used. The solution is compared against solutions using additional rotation criterion provided by additional RC.

14 efaMR

For example, with rotation = geomin, additional RC = c(CF-varimax), 'CF-quartimax', 'CF-quartimax', the geomin solution is compared against those with CF-varimax and CF-quartimax.

Estimation of standard errors and construction of confidence intervals are disabled with the function efaMR(). They are available with a function efa().

ssem	Simplifying Factor Strcutral Paths by Factor Rotation: Saturated Structural Equation Models

## **Description**

This function simplifies factor structural paths by factor rotation. We refer to the method as FSP or SSEM (saturated structural equation modeling). It re-parameterizes the obliquely rotated factor correlation matrix such that factors can be either endogenous or exogenous. In comparison, all factors are exogenous in exploratory factor analysis. Manifest variables can be normal variables, nonnormal variables, nonnormal continuous variable, Likert scale variables and time series. It also provides standard errors and confidence intervals for rotated factor loadings and structural parameters.

## Usage

```
ssem(x=NULL, factors=NULL, exfactors=1, covmat=NULL,
acm=NULL, n.obs=NULL, dist='normal', fm='ml', mtest = TRUE,
rotation='semtarget', normalize=FALSE, maxit=1000, geomin.delta=NULL,
MTarget=NULL, MWeight=NULL, BGWeight = NULL, BGTarget = NULL,
PhiWeight = NULL, PhiTarget = NULL, useorder=TRUE, se='sandwich',
LConfid=c(0.95,0.90), CItype='pse', Ib=2000, mnames=NULL, fnames=NULL,
merror='YES', wxt2 = 1e0)
```

## **Arguments**

X	The raw data: an n-by-p matrix where n is number of participants and p is the number of manifest variables.
factors	The number of factors m: specified by a researcher; the default one is the Kaiser rule which is the number of eigenvalues of covmat larger than one.
exfactors	The number of exogenous factors: 1 (default)
covmat	A p-by-p manifest variable correlation matrix.
acm	A $p(p-1)/2$ by $p(p-1)/2$ asymptotic covariance matrix of correlations: specified by the researcher.
n.obs	The number of participants used in calculating the correlation matrix. This is not required when the raw data $(x)$ is provided.
dist	Manifest variable distributions: 'normal'(default), 'continuous', 'ordinal' and 'ts'. 'normal' stands for normal distribution. 'continuous' stands for nonnormal continuous distributions. 'ordinal' stands for Likert scale variable. 'ts' stands for distributions for time-series data.
fm	Factor extraction methods: 'ml' (default) and 'ols'
mtest	Whether the test statistic is computed: TRUE (default) and FALSE

rotation Factor rotation criteria: 'semtarget' (default), 'CF-varimax', 'CF-quartimax', 'CFequamax', 'CF-parsimax', 'CF-facparsim', 'target', and 'geomin'. These rotation criteria can be used in both orthogonal and oblique rotation. In addition, a fifth rotation criterion 'xtarget' (extended target) rotation is available for oblique rotation. The ssem target rotation allows targets to be specified on both factor loadings and factor structural parameters. normalize Row standardization in factor rotation: FALSE (default) and TRUE (Kaiser standardization). maxit Maximum number of iterations in factor rotation: 1000 (default) The controlling parameter in Geomin rotation, 0.01 as the default value. geomin.delta MTarget The p-by-m target matrix for the factor loading matrix in target rotation and semtarget rotation. MWeight The p-by-m weight matrix for the factor loading matrix in target rotation and semtarget rotation. Optional BGWeight The m1-by-m weight matrix for the [Beta | Gamma] matrix in semtarget rotation (see details) Optional BGTarget The m1-by-m target matrix for the [Beta | Gamma] matrix in semtarget rotation where m1 is the number of endogenous factors (see details) PhiWeight The m2-by-m2 target matrix for the exogenous factor correlation matrix in semtarget rotation.Optional PhiTarget The m2-by-m2 weight matrix for the exogenous factor correlation matrix in semtarget rotation useorder Whether an order matrix is used for factor alignment: TRUE (default) and **FALSE** se Methods for estimating standard errors for rotated factor loadings and factor correlations, 'sandwich' (default), 'information', 'bootstrap', and 'jackknife'. The 'bootstrap' and 'jackknife' methods require raw data. Confidence levels for model parameters (rotated factor loadings and structural LConfid parameters) and RMSEA, respectively: c(.95, .90) as default. CItype Type of confidence intervals: 'pse' (default) or 'percentile'. CIs with 'pse' are based on point and standard error estimates; CIs with 'percentile' are based on bootstrap percentiles. Ιb The Number of bootstrap samples when se='bootstrap': 2000 (default) mnames Names of p manifest variables: Null (default) Names of m factors: Null (default) fnames Model error: 'YES' (default) or 'NO'. In general, we expect our model is a merror parsimonious representation to the complex real world. Thus, some amount of model error is unavailable. When merror = 'NO', the ssem model is assumed to fit perfectly in the population. The relative weight for structural parameters in 'semtarget' rotation: 1 (default) wxt2

#### **Details**

The function ssem conducts saturated structural equation modeling (ssem) in a variety of conditions. Data can be normal variables, non-normal continuous variables, and Likert variables. Our implementation of SSEM includes three major steps: factor extraction, factor rotation, and estimating standard errors for rotated factor loadings and factor correlations.

17

Factors can be extracted using two methods: maximum likelihood estimation (ml) and ordinary least squares (ols). These factor loading matrices are referred to as unrotated factor loading matrices. The ml unrotated factor loading matrix is obtained using factanal. The ols unrotated factor loading matrix is obtained using optim where the residual sum of squares is minimized. The starting values for communalities are squared multiple correlations (SMCs). The test statistic and model fit measures are provided.

Eight rotation criteria (semtarget, CF-varimax, CF-quartimax, CF-equamax, CF-parsimax, CF-facparsim, target, and geomin) are available for oblique rotation (Browne, 2001). Additionally, a new rotation criteria, ssemtarget, can be specified for oblique rotation. The factor rotation methods are achieved by calling functions in the package GPArotation. CF-varimax, CF-quartimax, CF-equamax, CF-parsimax, and CF-facparsim are members of the Crawford-Fugersion family (Crawford, & Ferguson, 1970) whose kappa = 1/p and kappa = 0, respectively. The target matrix in target rotation can either be a fully specified matrix or a partially specified matrix. Target rotation can be considered as a procedure which is located between EFA and CFA. In CFA, if a factor loading is specified to be zero, its value is fixed to be zero; if target rotation, if a factor loading is specified to be zero, it is made to zero as close as possible. In xtarget rotation, target values can be specified on both factor loadings and factor correlations. In ssemtarget, target values can be specified for the [Beta | Gamma] matrix where Beta is the regression weights of the endogenous factors on itself and the Gamma is the regression weights of the endogenous factors.

Confidence intervals for rotated factor loadings and correlation matrices are constructed using point estimates and their standard error estimates. Standard errors for rotated factor loadings and factor correlations are computed using a sandwich method (Ogasawara, 1998; Yuan, Marshall, & Bentler, 2002), which generalizes the augmented information method (Jennrich, 1974). The sandwich standard error are consistent estimates even when the data distribution is non-normal and model error exists in the population. Sandwich standard error estimates require a consistent estimate of the asymptotic covariance matrix of manifest variable correlations. Such estimates are described in Browne & Shapiro (1986) for non-normal continuous variables and in Yuan & Schuster (2013) for Likert variables. Estimation of the asymptotic covariance matrix of polychoric correlations is slow if the EFA model involves a large number of Likert variables.

When manifest variables are normally distributed (dist = 'normal') and model error does not exist (merror = 'NO'), the sandwich standard errors are equivalent to the usual standard error estimates, which come from the inverse of the information matrix. The information standard error estimates in EFA is available CEFA (Browne, Cudeck, Tateneni, & Mels, 2010) and SAS Proc Factor. Mplus (Muthen & Muthen, 2015) also implemented a version of sandwich standard errors for EFA, which are robust against non-normal distribution but not model error. Sandwich standard errors computed in efa tend to be larger than those computed in Mplus. Sandwich standard errors for non-normal distributions and with model error are equivalent to the infinitesimal jackknife standard errors described in Zhang, Preacher, & Jennrich (2012). Two computationally intensive standard error methods (se='bootstrap' and se='jackknife') are also implemented. More details on standard error estimation methods in EFA are documented in Zhang (2014).

#### Value

An object of class ssem, which includes:

details summary information about the analysis such as number of manifest variables,

number of factors, number of endogenous factors, number of exogenous factors, sample size, distribution, factor extraction method, factor rotation method, target values for target rotation, xtarget rotation and ssemtarget rotation, and levels for

confidence intervals.

unrotated the unrotated factor loading matrix

fdiscrepancy discrepancy function value used in factor extraction

convergence whether the factor extraction stage converged successfully, successful conver-

gence indicated by 0

heywood the number of heywood cases

nq the number of effective parameters

compsi contains eigenvalues, SMCs, communalities, and unique variances

R0 the sample correlation matrix

Phat the model implied correlation matrix

Residual the residual correlation matrix rotated the rotated factor loadings

Phi the rotated factor correlations

BG the [Beta | Gamma] latent regression coefficients

psi the endogenous residuals
Phi.xi the exogenous correlation

rotatedse the standard errors for rotated factor loadings

Phise the standard errors for rotated factor correlations

BGse the standard errors for the [Beta | Gamma] latent regression coefficients

psise the standard errors for the endogenous residuals
Phi.xise the standard errors for the exogenous correlation

ModelF the test statistic and measures of model fit

rotatedlow the lower bound of confidence levels for factor loadings
rotatedupper the upper bound of confidence levels for factor loadings
Philow the lower bound of confidence levels for factor correlations
Philopper the lower bound of confidence levels for factor correlations

BGlower the lower bound of the [Beta | Gamma] latent regression coefficients

BGupper the upper bound of the [Beta | Gamma] latent regression coefficients

psilower the lower bound of the endogenous residuals
psiupper the upper bound of the endogenous residuals
Phixilower the lower bound of the exogenous correlation
Phixiupper the upper bound of the exogenous correlation
