Principal component analysis

Description

Principal component analysis

Usage

```
 \begin{array}{l} \mathsf{acp}(\mathsf{x},\mathsf{center} = \mathsf{TRUE},\mathsf{reduce} = \mathsf{TRUE},\mathsf{wI} = \mathsf{rep}(1,\mathsf{nrow}(\mathsf{x})),\mathsf{wV} = \mathsf{rep}(1,\mathsf{ncol}(\mathsf{x}))) \\ \mathsf{pca}(\mathsf{x},\mathsf{center} = \mathsf{TRUE},\mathsf{reduce} = \mathsf{TRUE},\mathsf{wI} = \mathsf{rep}(1,\mathsf{nrow}(\mathsf{x})),\mathsf{wV} = \mathsf{rep}(1,\mathsf{ncol}(\mathsf{x}))) \\ \#\# \ \mathsf{S3} \ \mathsf{method} \ \mathsf{for} \ \mathsf{class} \ \mathsf{'acp'} \\ \mathsf{print}(\mathsf{x}, \ \ldots) \\ \end{array}
```

Arguments

Χ	Matrix / data frame
center	a logical value indicating whether we center data
reduce	a logical value indicating whether we "reduce" data i.e. divide each column by standard deviation
wI, wV	weigth vector for individuals / variables
	arguments to be passed to or from other methods.

Details

This function offer a variant of princomp and prcomp functions, with a slightly different graphic representation (see plot.acp).

Value

An object of class **acp** The object is a list with components:

sdev	the standard deviations of the principal components.
loadings	the matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors). This is of class "loadings": see loadings for its print method.
scores	if scores = TRUE, the scores of the supplied data on the principal components.
eig	Eigen values

acpgen

Generalised principal component analysis

Description

Generalised principal component analysis

Usage

```
acpgen(x,h1,h2,center=TRUE,reduce=TRUE,kernel="gaussien")
K(u,kernel="gaussien")
W(x,h,D=NULL,kernel="gaussien")
```

Arguments

X	Matrix or data frame
h	Scalar: bandwidth of the Kernel
h1	Scalar: bandwidth of the Kernel for W
h2	Scalar: bandwidth of the Kernel for U
kernel	The kernel used. This must be one of '"gaussien"', '"quartic"', '"triweight"', '"epanechikov"', '"cosinus"' or '"uniform"'
center	A logical value indicating whether we center data
reduce	A logical value indicating whether we "reduce" data i.e. divide each column by standard deviation
D	A product scalar matrix / une matrice de produit scalaire
u	Vector

Details

acpgen compute generalised pca. i.e. spectral analysis of $U_n.W_n^{-1}$, and project X_i with W_n^{-1} on the principal vector sub-spaces.

 X_i a column vector of p variables of individu i (input data)

W compute estimation of noise in the variance.

$$W_n = \frac{\sum_{i=1}^{n-1} \sum_{j=i+1}^{n} K(||X_i - X_j||_{V_n^{-1}}/h)(X_i - X_j)(X_i - X_j)'}{\sum_{i=1}^{n-1} \sum_{j=i+1}^{n} K(||X_i - X_j||_{V_n^{-1}}/h)}$$

with V_n variance estimation;

4 acpgen

U compute robust variance. $U_n^{-1} = S_n^{-1} - 1/hV_n^{-1}$

$$S_n = \frac{\sum_{i=1}^n K(||X_i||_{V_n^{-1}}/h)(X_i - \mu_n)(X_i - \mu_n)'}{\sum_{i=1}^n K(||X_i||_{V_n^{-1}}/h)}$$

with μ_n estimator of the mean.

K compute kernel, i.e.

gaussien:

 $\frac{1}{\sqrt{2\pi}}e^{-u^2/2}$

quartic:

 $\frac{15}{16}(1-u^2)^2I_{|u|\leq 1}$

triweight:

 $\frac{35}{32}(1-u^2)^3I_{|u|\leq 1}$

epanechikov:

 $\frac{3}{4}(1-u^2)I_{|u|\leq 1}$

cosinus:

 $\frac{\pi}{4}\cos(\frac{\pi}{2}u)I_{|u|\leq 1}$

Value

An object of class **acp** The object is a list with components:

sdev the standard deviations of the principal components.

loadings the matrix of variable loadings (i.e., a matrix whose columns contain the eigen-

vectors). This is of class "loadings": see loadings for its print method.

scores if scores = TRUE, the scores of the supplied data on the principal components.

eig Eigen values

```

acprob

Robust principal component analysis

Description

Robust principal component analysis

Usage

```
acprob(x,h,center=TRUE,reduce=TRUE,kernel="gaussien")
```

Arguments

x	Matrix / data frame
h	Scalar: bandwidth of the Kernel
kernel	The kernel used. This must be one of '"gaussien"', '"quartic"', '"triweight"', '"epanechikov"', '"cosinus"' or '"uniform"'
center	A logical value indicating whether we center data
reduce	A logical value indicating whether we "reduce" data i.e. divide each column by standard deviation

Details

acpgen compute robust pca. i.e. spectral analysis of a robust variance instead of usual variance. Robust variance: see varrob

6 afc

Value

An object of class **acp** The object is a list with components:

sdev the standard deviations of the principal components.

loadings the matrix of variable loadings (i.e., a matrix whose columns contain the eigen-

vectors). This is of class "loadings": see loadings for its print method.

scores if scores = TRUE, the scores of the supplied data on the principal components.

eig Eigen values

princomp acpgen

afc Correspondance factorial analysis.

Description

Compute an acp on a contingency table tacking into account weight of rows and columns

Usage

afc(x)

Arguments

x A contingency table, or a result of function burt or matlogic

burt 7

Author(s)

Antoine Lucas

Examples

```
## Not run:
color <- as.factor(c('blue','red','red','blue','red'))
size <- as.factor(c('large','large','small','medium','large'))
x <- data.frame(color,size)

afc.1 <- afc(burt(x))
afc.2 <- afc(matlogic(x))

plotAll(afc.1)
plotAll(afc.2)

## End(Not run)</pre>
```

burt

Compute burt table from a factor dataframe.

Description

matlogic returns for all variables a matrix of logical values for each levels. burt is defined as t(matlogic).matlogic

Usage

```
burt(x)
matlogic(x)
```

Arguments

Х

A dataframe that contents only factors

Author(s)

Antoine Lucas

Examples

8 diss

##3	0	1	0	0	1	
##4	1	0	0	1	0	
##5	0	1	1	0	0	
bur	t(x)					
##		color.blue	${\tt color.red}$	size.large	$\verb"size.medium"$	$\verb size.small $
##	color.blue	2	0	1	1	0
##	color.red	0	3	2	0	1
##	size.large	1	2	3	0	0
##	size.medium	1	0	0	1	0
##	size.small	0	1	0	0	1

diss

Compute a dissimilarity matrix

Description

Compute a dissimilarity matrix from a data set (containing only factors).

Usage

```
diss(x, w=rep(1, ncol(x)))
```

Arguments

x A matrix or data frame containing only factors.

w A vector of weight, by default each variable has got same weight

Details

Case of N individuals described by P categorical variables: each element (i,j) of the signed similarities array is computed by sommation over the P variables of the contributions of each variable, multiplied by the weight of the variable. The contribution of a given categorical variable is +1 if the individual i and j are in the same class, and is -1 if they are not.

Value

A dissimilarity matrix.

Author(s)

Antoine Lucas

        ,2,4,3,3,2
        ,1,2,4,2,1
        ,2,3,2,3,1),ncol=5,byrow=TRUE)
diss(data)
## With weights
diss(data,w=c(1,1,2,2,3))
```

Dist

Distance Matrix Computation

Description

This function computes and returns the distance matrix computed by using the specified distance measure to compute the distances between the rows of a data matrix.

Usage

```
Dist(x, method = "euclidean", nbproc = 2, diag = FALSE, upper = FALSE)
```

Arguments

X	numeric matrix or (data frame) or an object of class "exprSet". Distances between the rows of x will be computed.
method	the distance measure to be used. This must be one of "euclidean", "maximum", "manhattan", "canberra", "binary", "pearson", "abspearson", "correlation", "abscorrelation", "spearman" or "kendall". Any unambiguous substring can be given.
nbproc	integer, Number of subprocess for parallelization
diag	logical value indicating whether the diagonal of the distance matrix should be printed by print.dist.
upper	logical value indicating whether the upper triangle of the distance matrix should be printed by print.dist.

Details

Available distance measures are (written for two vectors x and y):

euclidean: Usual square distance between the two vectors (2 norm).

maximum: Maximum distance between two components of x and y (supremum norm)

10 Dist

manhattan: Absolute distance between the two vectors (1 norm).

canberra: $\sum_i |x_i - y_i|/|x_i + y_i|$. Terms with zero numerator and denominator are omitted from the sum and treated as if the values were missing.

binary: (aka *asymmetric binary*): The vectors are regarded as binary bits, so non-zero elements are 'on' and zero elements are 'off'. The distance is the *proportion* of bits in which only one is on amongst those in which at least one is on.

pearson: Also named "not centered Pearson" $1 - \frac{\sum_i x_i y_i}{\sqrt{\sum_i x_i^2 \sum_i y_i^2}}$.

abspearson: Absolute Pearson $1 - \left| \frac{\sum_i x_i y_i}{\sqrt{\sum_i x_i^2 \sum_i y_i^2}} \right|$.

correlation: Also named "Centered Pearson" 1 - corr(x, y).

abscorrelation: Absolute correlation 1 - |corr(x, y)| with

$$corr(x,y) = \frac{\sum_{i} x_{i} y_{i} - \frac{1}{n} \sum_{i} x_{i} \sum_{i} y_{i}}{\sqrt{\left(\sum_{i} x_{i}^{2} - \frac{1}{n} \left(\sum_{i} x_{i}\right)^{2}\right)\left(\sum_{i} y_{i}^{2} - \frac{1}{n} \left(\sum_{i} y_{i}\right)^{2}\right)}}.$$

spearman: Compute a distance based on rank. $\sum (d_i^2)$ where d_i is the difference in rank between x_i and y_i .

Dist(x,method="spearman")[i,j] =

cor.test(x[i,],x[j,],method="spearman")\$statistic

kendall: Compute a distance based on rank. $\sum_{i,j} K_{i,j}(x,y)$ with $K_{i,j}(x,y)$ is 0 if x_i, x_j in same order as $y_i, y_j, 1$ if not.

Missing values are allowed, and are excluded from all computations involving the rows within which they occur. If some columns are excluded in calculating a Euclidean, Manhattan or Canberra distance, the sum is scaled up proportionally to the number of columns used. If all pairs are excluded when calculating a particular distance, the value is NA.

The functions as.matrix.dist() and as.dist() can be used for conversion between objects of class "dist" and conventional distance matrices and vice versa.

Value

An object of class "dist".

The lower triangle of the distance matrix stored by columns in a vector, say do. If n is the number of observations, i.e., n <- attr(do, "Size"), then for i < j <= n, the dissimilarity between (row) i and j is do[n*(i-1) - i*(i-1)/2 + j-i]. The length of the vector is n * (n-1)/2, i.e., of order n^2 .

The object has the following attributes (besides "class" equal to "dist"):

Size integer, the number of observations in the dataset.

Labels optionally, contains the labels, if any, of the observations of the dataset.

Diag, Upper logicals corresponding to the arguments diag and upper above, specifying how

the object should be printed.

call optionally, the call used to create the object.

methods optionally, the distance method used; resulting form dist(), the (match.arg()ed)

method argument.

hcluster 11

Note

Multi-thread (parallelisation) is disable on Windows.

```

See Also

daisy in the 'cluster' package with more possibilities in the case of *mixed* (contiuous / categorical) variables. dist hcluster.

Examples

```
x <- matrix(rnorm(100), nrow=5)
Dist(x)
Dist(x, diag = TRUE)
Dist(x, upper = TRUE)

## compute dist with 8 threads
Dist(x,nbproc=8)

Dist(x,method="abscorrelation")
Dist(x,method="kendall")</pre>
```

hcluster

Hierarchical Clustering

Description

Hierarchical cluster analysis.

Usage

Arguments

Х

A numeric matrix of data, or an object that can be coerced to such a matrix (such as a numeric vector or a data frame with all numeric columns). Or an object of class "exprSet".

12 hcluster

method the distance measure to be used. This must be one of "euclidean", "maximum",

"manhattan", "canberra", "binary", "pearson", "abspearson", "correlation",

"abscorrelation", "spearman" or "kendall". Any unambiguous substring

can be given.

diag logical value indicating whether the diagonal of the distance matrix should be

printed by print.dist.

upper logical value indicating whether the upper triangle of the distance matrix should

be printed by print.dist.

link the agglomeration method to be used. This should be (an unambiguous abbre-

viation of) one of "ward", "single", "complete", "average", "mcquitty",

"median" or "centroid", "centroid2", "ward.d2".

members NULL or a vector with length size of d.

nbproc integer, number of subprocess for parallelization [Linux & Mac only]

doubleprecision

True: use of double precision for distance matrix computation; False: use simple

precision

Details

This function is a mix of function helust and function dist. heluster(x, method = "euclidean", link = "complete") = helust(dist(x, method = "euclidean"), method = "complete")) It use twice less memory, as it doesn't store distance matrix.

For more details, see documentation of hclust and Dist.

Value

An object of class **hclust** which describes the tree produced by the clustering process. The object is a list with components:

merge an n-1 by 2 matrix. Row i of merge describes the merging of clusters at step i

of the clustering. If an element j in the row is negative, then observation -j was merged at this stage. If j is positive then the merge was with the cluster formed at the (earlier) stage j of the algorithm. Thus negative entries in merge indicate agglomerations of singletons, and positive entries indicate agglomerations of

non-singletons.

height a set of n-1 non-decreasing real values. The clustering *height*: that is, the

value of the criterion associated with the clustering method for the particular

agglomeration.

order a vector giving the permutation of the original observations suitable for plotting,

in the sense that a cluster plot using this ordering and matrix merge will not have

crossings of the branches.

labels labels for each of the objects being clustered.

call the call which produced the result.
method the cluster method that has been used.

dist.method the distance that has been used to create d (only returned if the distance object

has a "method" attribute).

hcluster 13

There is a print and a plot method for helust objects. The plclust() function is basically the same as the plot method, plot.hclust, primarily for back compatibility with S-plus. Its extra arguments are not yet implemented.

Note

Multi-thread (parallelisation) is disable on Windows.

Author(s)

The hcluster function is based on C code adapted from Cran Fortran routine by Antoine Lucas.

```

Kmeans

K-Means Clustering

Description

Perform k-means clustering on a data matrix.

Usage

Arguments

X	A numeric matrix of data, or an object that can be coerced to such a matrix (such as a numeric vector or a data frame with all numeric columns). Or an object of class "exprSet".
centers	Either the number of clusters or a set of initial cluster centers. If the first, a random set of rows in x are chosen as the initial centers.
iter.max	The maximum number of iterations allowed.
nstart	If centers is a number, how many random sets should be chosen?
method	the distance measure to be used. This must be one of "euclidean", "maximum", "manhattan", "canberra", "binary", "pearson", "abspearson", "abscorrelation", "correlation", "spearman" or "kendall". Any unambiguous substring can be given.

Kmeans 15

Details

The data given by x is clustered by the k-means algorithm. When this terminates, all cluster centres are at the mean of their Voronoi sets (the set of data points which are nearest to the cluster centre).

The algorithm of Lloyd-Forgy is used; method="euclidean" should return same result as with function kmeans.

Value

A list with components:

cluster A vector of integers indicating the cluster to which each point is allocated.

centers A matrix of cluster centres.

withinss The within-cluster sum of square distances for each cluster.

size The number of points in each cluster.

Note

An objective: to allow NA values.

VarRob

Robust variance

Description

Compute a robust variance

Usage

```
varrob(x,h,D=NULL,kernel="gaussien")
```

Arguments

x Matrix / data frame

h Scalar: bandwidth of the Kernel

kernel The kernel used. This must be one of '"gaussien"', '"quartic"', '"triweight"',

"epanechikov", "cosinus" or "uniform"

D A product scalar matrix / une matrice de produit scalaire

Details

U compute robust variance. $U_n^{-1} = S_n^{-1} - 1/hV_n^{-1}$

$$S_n = \frac{\sum_{i=1}^n K(||X_i||_{V_n^{-1}}/h)(X_i - \mu_n)(X_i - \mu_n)'}{\sum_{i=1}^n K(||X_i||_{V_n^{-1}}/h)}$$

with μ_n estimator of the mean.

K compute a kernel.

Value

A matrix
