Description

This package provides detailed functionality for working with the univariate and multivariate Generalized Hyperbolic distribution and its special cases (Hyperbolic (hyp), Normal Inverse Gaussian (NIG), Variance Gamma (VG), skewed Student-t and Gaussian distribution). Especially, it contains fitting procedures, an AIC-based model selection routine, and functions for the computation of density, quantile, probability, random variates, expected shortfall and some portfolio optimization and plotting routines as well as the likelihood ratio test. In addition, it contains the Generalized Inverse Gaussian distribution.

Details

Initialize:

ghyp Initialize a generalized hyperbolic distribution.
hyp Initialize a hyperbolic distribution.

NIG Initialize a normal inverse gaussian distribution.

VG Initialize a variance gamma distribution.

student.t Initialize a Student-t distribution.

Initialize a Gaussian distribution.

Density, distribution function, quantile function and random generation:

dghyp
 pghyp
 qghyp
 pghyp
 qghyp
 rghyp
 Random generation of a generalized hyperbolic distribution.
 Random generation of a generalized hyperbolic distribution.

Fit to data:

fit.ghypuv Fit a generalized hyperbolic distribution to univariate data. fit.hypuv Fit a hyperbolic distribution to univariate data. fit.NIGuv Fit a normal inverse gaussian distribution to univariate data. Fit a variance gamma distribution to univariate data. fit. VGuv Fit a skewed Student-t distribution to univariate data. fit.tuv fit.gaussuv Fit a Gaussian distribution to univariate data. fit.ghypmv Fit a generalized hyperbolic distribution to multivariate data. Fit a hyperbolic distribution to multivariate data. fit.hypmv fit.NIGmv Fit a normal inverse gaussian distribution to multivariate data. Fit a variance gamma distribution to multivariate data. fit.VGmv fit.tmv Fit a skewed Student-t distribution to multivariate data. fit.gaussmv Fit a Gaussian distribution to multivariate data. Perform a model selection based on the AIC. stepAIC.ghyp

Risk, performance and portfolio optimization:

ESghyp Expected shortfall of a univariate generalized hyperbolic distribution. ghyp.omega Performance measure *Omega* based on a univariate ghyp distribution. portfolio.optimize Calculate optimal portfolios with respect to alternative risk measures.

Utilities:

mean Returns the expected value.
vcov Returns the variance(-covariance).

ghyp.skewness Skewness of a univariate ghyp distribution.

ghyp.kurtosis Kurtosis of a univariate ghyp distribution.

Returns Log-Likelihood of fitted ghyp objects.

AIC Returns the Akaike's Information Criterion of fitted ghyp objects.

lik.ratio.test Performs a likelihood-ratio test on fitted ghyp distributions.

Extract certain dimensions of a multivariate ghyp distribution.

scale Scale ghyp distribution objects to zero expectation and/or unit variance.

transform Transform a multivariate generalized hyperbolic distribution.

ghyp.moment Moments of the univariate ghyp distribution.

coef Parameters of a generalized hyperbolic distribution.

ghyp.data Data of a (fitted) generalized hyperbolic distribution.

ghyp.fit.info Information about the fitting procedure, log-likelihood and AIC value.

ghyp. name Returns the name of the ghyp distribution or a subclass of it.

ghyp.dim Returns the dimension of a ghyp object.

summary Summary of a fitted generalized hyperbolic distribution.

Plot functions:

qqghyp Perform a quantile-quantile plot of a (fitted) univariate ghyp distribution.

Plot a histogram of a (fitted) univariate generalized hyperbolic distribution.

Produce a matrix of scatterplots with quantile-quantile plots on the diagonal.

Plot the density of a univariate ghyp distribution.

Add the density of a univariate ghyp distribution to a graphics device.

Generalized inverse gaussian distribution:

dgig Density of a generalized inverse gaussian distribution
pgig Distribution function of a generalized inverse gaussian distribution
qgig Quantile of a generalized inverse gaussian distribution
ESgig Expected shortfall of a generalized inverse gaussian distribution
rgig Random generation of a generalized inverse gaussian distribution

Package vignette:

A document about generalized hyperbolic distributions can be found in the doc folder of this package or on https://cran.r-project.org/package=ghyp.

Existing solutions

There are packages like GeneralizedHyperbolic, HyperbolicDist, SkewHyperbolic, VarianceGamma and fBasics which cover the univariate generalized hyperbolic distribution and/or some of its special cases. However, the univariate case is contained in this package as well because we aim to provide a uniform interface to deal with generalized hyperbolic distribution. Recently an R port of the S-Plus library QRMlib was released. The package QRMlib contains fitting procedures for the multivariate NIG, hyp and skewed Student-t distribution but not for the generalized hyperbolic case. The package fMultivar implements a fitting routine for multivariate skewed Student-t distributions as well.

Object orientation

We follow an object-oriented programming approach in this package and introduce distribution objects. There are mainly four reasons for that:

- Unlike most distributions the GH distribution has quite a few parameters which have to fulfill some consistency requirements. Consistency checks can be performed uniquely when an object is initialized.
- Once initialized the common functions belonging to a distribution can be called conveniently by passing the distribution object. A repeated input of the parameters is avoided.
- Distributions returned from fitting procedures can be directly passed to, e.g., the density function since fitted distribution objects add information to the distribution object and consequently inherit from the class of the distribution object.
- Generic method dispatching can be used to provide a uniform interface to, e.g., plot the probability density of a specific distribution like plot(distribution.object). Additionally, one can take advantage of generic programming since R provides virtual classes and some forms of polymorphism.

Acknowledgement

This package has been partially developed in the framework of the COST-P10 "Physics of Risk" project. Financial support by the Swiss State Secretariat for Education and Research (SBF) is gratefully acknowledged.

6 coef-method

coef-method

Extract parameters of generalized hyperbolic distribution objects

Description

The function coef returns the parameters of a generalized hyperbolic distribution object as a list. The user can choose between the "chi/psi", the "alpha.bar" and the "alpha/delta" parametrization. The function coefficients is a synonym for coef.

Usage

```
## S4 method for signature 'ghyp'
coef(object, type = c("chi.psi", "alpha.bar", "alpha.delta"))
## S4 method for signature 'ghyp'
coefficients(object, type = c("chi.psi", "alpha.bar", "alpha.delta"))
```

Arguments

object An object inheriting from class ghyp.

type According to type the parameters of either the "chi/psi", the "alpha.bar" or the

"alpha/delta" parametrization will be returned. If type is missing, the parame-

ters belonging to the parametrization of the construction are returned.

Details

Internally, the "chi/psi" parametrization is used. However, fitting is only possible in the "alpha.bar" parametrization as it provides the most convenient parameter constraints.

Value

If type is "chi.psi" a list with components:

lambda Shape parameter.
chi Shape parameter.
psi Shape parameters.
mu Location parameter.
sigma Dispersion parameter.
gamma Skewness parameter.

If type is "alpha.bar" a list with components:

lambda Shape parameter.
alpha.bar Shape parameter.
mu Location parameter.
sigma Dispersion parameter.

ESghyp.attribution 7

gamma Skewness parameter.

If type is "alpha.delta" a list with components:

```
lambda Shape parameter.
alpha Shape parameter.
delta Shape parameter.
mu Location parameter.
Delta Dispersion matrix with a determinant of 1 (only returned in the multivariate case).
beta Shape and skewness parameter.
```

Note

A switch from either the "chi/psi" to the "alpha.bar" or from the "alpha/delta" to the "alpha.bar" parametrization is not yet possible.

```

Examples

ESghyp.attribution

Risk attribution.

Description

Functions to get the *contribution* of each asset to the portfolio's *Expected Shortfall* based on multivariate generalized hyperbolic distributions as well as the expected shortfall *sensitivity* to marginal changes in portfolio allocation.

8 ESghyp.attribution

Usage

```
ESghyp.attribution(
  alpha,
  object = ghyp(),
  distr = c("return", "loss"),
  weights = NULL,
   ...
)
```

Arguments

alpha a vector of confidence levels for ES.

object a multivariate fitted ghyp object inheriting from class ghyp.

distr whether the ghyp-object specifies a return or a loss-distribution (see **Details**).

weights vector of portfolio weights. Default is an equally-weighted portfolio.

optional arguments passed from ghyp attribution to gghyp and integrate.

Details

The parameter distr specifies whether the ghyp-object describes a return or a loss-distribution. In case of a return distribution the expected-shortfall on a confidence level α is defined as $\mathrm{ES}_\alpha := \mathrm{E}(X|X \le F_X^{-1}(\alpha))$ while in case of a loss distribution it is defined on a confidence level α as $\mathrm{ES}_\alpha := \mathrm{E}(X|X > F_X^{-1}(\alpha))$.

Value

ESghyp. attribution is an object of class ghyp. attribution.

```
portfolio.attrib <- ESghyp.attribution(alpha=es.levels, object=assets.fit, weights=weights)
## End(Not run)</pre>
```

fit.ghypmv

Fitting generalized hyperbolic distributions to multivariate data

Description

Perform a maximum likelihood estimation of the parameters of a multivariate generalized hyperbolic distribution by using an Expectation Maximization (EM) based algorithm.

Usage

```
fit.ghypmv(data, lambda = 1, alpha.bar = 1, mu = NULL, sigma = NULL,
          gamma = NULL, opt.pars = c(lambda = TRUE, alpha.bar = TRUE, mu = TRUE,
                                       sigma = TRUE, gamma = !symmetric),
           symmetric = FALSE, standardize = FALSE, nit = 2000, reltol = 1e-8,
          abstol = reltol * 10, na.rm = FALSE, silent = FALSE, save.data = TRUE,
           trace = TRUE, ...)
fit.hypmv(data,
      opt.pars = c(alpha.bar = TRUE, mu = TRUE, sigma = TRUE, gamma = !symmetric),
          symmetric = FALSE, ...)
fit.NIGmv(data,
      opt.pars = c(alpha.bar = TRUE, mu = TRUE, sigma = TRUE, gamma = !symmetric),
          symmetric = FALSE, ...)
fit.VGmv(data, lambda = 1,
       opt.pars = c(lambda = TRUE, mu = TRUE, sigma = TRUE, gamma = !symmetric),
         symmetric = FALSE, ...)
fit.tmv(data, nu = 3.5,
       opt.pars = c(lambda = TRUE, mu = TRUE, sigma = TRUE, gamma = !symmetric),
        symmetric = FALSE, ...)
fit.gaussmv(data, na.rm = TRUE, save.data = TRUE)
```

Arguments

An object coercible to a matrix.

Starting value for the shape parameter lambda.

Starting value for the shape parameter alpha.bar.

Starting value for the shape parameter nu (only used in case of a student-t distribution. It determines the degree of freedom and is defined as -2*lambda.)

10 fit.ghypmv

mu	Starting value for the location parameter mu.
sigma	Starting value for the dispersion matrix sigma.
gamma	Starting value for the skewness vecotr gamma.
opt.pars	A named logical vector which states which parameters should be fitted.
symmetric	If TRUE the skewness parameter gamma keeps zero.
standardize	If TRUE the sample will be standardized before fitting. Afterwards, the parameters and log-likelihood et cetera will be back-transformed.
save.data	If TRUE data will be stored within the mle.ghyp object (cf. ghyp.data).
trace	If TRUE the evolution of the parameter values during the fitting procedure will be traced and stored (cf. ghyp.fit.info).
na.rm	If TRUE missing values will be removed from data.
silent	If TRUE no prompts will appear in the console.
nit	Maximal number of iterations of the expectation maximation algorithm.
reltol	Relative convergence tolerance.
abstol	Absolute convergence tolerance.
	Arguments passed to optim and to fit.ghypmv when fitting special cases of the

Details

This function uses a modified EM algorithm which is called Multi-Cycle Expectation Conditional Maximization (MCECM) algorithm. This algorithm is sketched in the vignette of this package which can be found in the doc folder. A more detailed description is provided by the book *Quantitative Risk Management, Concepts, Techniques and Tools* (see "References").

generalized hyperbolic distribution.

The general-purpose optimization routine optim is used to maximize the loglikelihood function of the univariate mixing distribution. The default method is that of Nelder and Mead which uses only function values. Parameters of optim can be passed via the ... argument of the fitting routines.

Value

An object of class mle.ghyp.

Note

The variance gamma distribution becomes singular when $\mathbf{x} - \mu = 0$. This singularity is catched and the reduced density function is computed. Because the transition is not smooth in the numerical implementation this can rarely result in nonsensical fits.

Providing both arguments, opt.pars and symmetric respectively, can result in a conflict when opt.pars['gamma'] and symmetric are TRUE. In this case symmetric will dominate and opt.pars['gamma'] is set to FALSE.

ghyp-constructors

Create generalized hyperbolic distribution objects

Description

Constructor functions for univariate and multivariate generalized hyperbolic distribution objects and their special cases in one of the parametrizations "chi/psi", "alpha.bar" and "alpha/delta".

Usage

```
ghyp(lambda = 0.5, chi = 0.5, psi = 2, mu = 0, sigma = diag(rep(1, length(mu))),
        gamma = rep(0, length(mu)), alpha.bar = NULL, data = NULL)

ghyp.ad(lambda = 0.5, alpha = 1.5, delta = 1, beta = rep(0, length(mu)),
        mu = 0, Delta = diag(rep(1, length(mu))), data = NULL)

hyp(chi = 0.5, psi = 2, mu = 0, sigma = diag(rep(1, length(mu))),
        gamma = rep(0, length(mu)), alpha.bar = NULL, data = NULL)

hyp.ad(alpha = 1.5, delta = 1, beta = rep(0, length(mu)), mu = 0,
        Delta = diag(rep(1, length(mu))), data = NULL)
```

```
NIG(chi = 2, psi = 2, mu = 0, sigma = diag(rep(1, length(mu))),
    gamma = rep(0, length(mu)), alpha.bar = NULL, data = NULL)

NIG.ad(alpha = 1.5, delta = 1, beta = rep(0, length(mu)), mu = 0,
    Delta = diag(rep(1, length(mu))), data = NULL)

student.t(nu = 3.5, chi = nu - 2, mu = 0, sigma = diag(rep(1, length(mu))),
    gamma = rep(0, length(mu)), data = NULL)

student.t.ad(lambda = -2, delta = 1, beta = rep(0, length(mu)), mu = 0,
    Delta = diag(rep(1, length(mu))), data = NULL)

VG(lambda = 1, psi = 2*lambda, mu = 0, sigma = diag(rep(1, length(mu))),
    gamma = rep(0, length(mu)), data = NULL)

VG.ad(lambda = 2, alpha = 1.5, beta = rep(0, length(mu)), mu = 0,
    Delta = diag(rep(1, length(mu))), data = NULL)

gauss(mu = 0, sigma = diag(rep(1, length(mu))), data = NULL)
```

Arguments

lambda	Shape parameter. Common for all parametrizations.
nu	Shape parameter only used in case of a Student-t distribution in the "chi/psi" and "alpha.bar" parametrization . It determines the degree of freedom.
chi	Shape parameter of the "chi/psi" parametrization.
psi	Shape parameter of the "chi/psi" parametrization.
alpha	Shape parameter of the "alpha/delta" parametrization.
delta	Shape parameter of the "alpha/delta" parametrization.
alpha.bar	Shape parameter of the "alpha.bar" parametrization. Supplying "alpha.bar" makes the parameters "chi" and "psi" redundant.
mu	Location parameter. Either a scalar or a vector. Common for all parametrizations.
sigma	Dispersion parameter of the "chi/psi" parametrization. Either a scalar or a matrix.
Delta	Dispersion parameter. Must be a matrix with a determinant of 1. This parameter is only used in the multivariate case of the "alpha.beta" parametrization.
gamma	Skewness parameter of the "chi/psi" parametrization. Either a scalar or a vector.
beta	Skewness parameter of the "alpha/delta" parametrization. Either a scalar or a vector.
data	An object coercible to a vector (univariate case) or matrix (multivariate case).

Details

These functions serve as constructors for univariate and multivariate objects.

ghyp, hyp and NIG are constructor functions for both the "chi/psi" and the "alpha.bar" parametrization. Whenever alpha.bar is not NULL it is assumed that the "alpha.bar" parametrization is used and the parameters "chi" and "psi" become redundant.

Similarly, the variance gamma (VG) and the Student-t distribution share the same constructor function for both the chi/psi and alpha.bar parametrization. To initialize them in the alpha.bar parametrization simply omit the argument psi and chi, respectively. If psi or chi are submitted, the "chi/psi" parametrization will be used.

ghyp.ad, hyp.ad, NIG.ad, student.t.ad and VG.ad use the "alpha/delta" parametrization.

The following table gives the constructors for each combination of distribution and parametrization.

		Parametrization	
Distribution	"chi/psi"	"alpha.bar"	"alpha/delta"
GH	ghyp()	<pre>ghyp(, alpha.bar=x)</pre>	ghyp.ad()
hyp	hyp()	<pre>hyp(, alpha.bar=x)</pre>	hyp.ad()
NIG	NIG()	NIG(, alpha.bar=x)	NIG.ad()
Student-t	<pre>student.t(, chi=x)</pre>	student.t()	<pre>student.t.ad()</pre>
VG	VG(, psi=x)	VG()	<pre>VG.ad()</pre>

Have a look on the vignette of this package in the doc folder for further information regarding the parametrization and for the domains of variation of the parameters.

Value

An object of class ghyp.

Note

The Student-t parametrization obtained via the "alpha.bar" parametrization slightly differs from the common Student-t parametrization: The parameter sigma denotes the standard deviation in the univariate case and the variance in the multivariate case. Thus, set $\sigma = \sqrt{\nu/(\nu-2)}$ in the univariate case to get the same results as with the standard R implementation of the Student-t distribution.

In case of non-finite variance, the "alpha.bar" parametrization does not work because sigma is defined to be the standard deviation. In this case the "chi/psi" parametrization can be used by submitting the parameter chi. To obtain equal results as the standard R implementation use student.t(nu = nu, chi = nu) (see **Examples**).

Have a look on the vignette of this package in the doc folder for further information.

Once an object of class ghyp is created the methods Xghyp have to be used even when the distribution is a special case of the GH distribution. E.g. do not use dVG. Use dghyp and submit a variance gamma distribution created with VG().

ghyp-distribution

The Generalized Hyperbolic Distribution

Description

Density, distribution function, quantile function, expected-shortfall and random generation for the univariate and multivariate generalized hyperbolic distribution and its special cases.

Usage

```
dghyp(x, object = ghyp(), logvalue = FALSE)

pghyp(q, object = ghyp(), n.sim = 10000, subdivisions = 200,
    rel.tol = .Machine$double.eps^0.5, abs.tol = rel.tol,
    lower.tail = TRUE)
```

18 ghyp-distribution

Arguments

р	A vector of probabilities.
X	A vector, matrix or data.frame of quantiles.
q	A vector, matrix or data.frame of quantiles.
n	Number of observations.
object	An object inheriting from class ghyp.
logvalue	If TRUE the logarithm of the density will be returned.
n.sim	The number of simulations when computing pghyp of a multivariate generalized hyperbolic distribution.
subdivisions	The number of subdivisions passed to integrate when computing the distribution function pghyp of a univariate generalized hyperbolic distribution.
rel.tol	The relative accuracy requested from integrate.
abs.tol	The absolute accuracy requested from integrate.
lower.tail	If TRUE (default), probabilities are $P[X \le x]$, otherwise, $P[X > x]$.
method	The method how quantiles are computed (see Details).
spline.points	The number of support points when computing the quantiles with the method "splines" instead of "integration".
root.tol	The tolerance of uniroot.

Details

qghyp only works for univariate generalized hyperbolic distributions.

pghyp performs a numeric integration of the density in the univariate case. The multivariate cumulative distribution is computed by means of monte carlo simulation.

qghyp computes the quantiles either by using the "integration" method where the root of the distribution function is solved or via "splines" which interpolates the distribution function and solves it with uniroot afterwards. The "integration" method is recommended when only few quantiles are required. If more than approximately 20 quantiles are needed to be calculated the "splines" method becomes faster. The accuracy can be controlled with an adequate setting of the parameters rel.tol, abs.tol, root.tol and spline.points.

rghyp uses the random generator for generalized inverse Gaussian distributed random variates from the Rmetrics package *fBasics* (cf. rgig).

ghyp-distribution 19

Value

```
dghyp gives the density,
pghyp gives the distribution function,
qghyp gives the quantile function,
rghyp generates random deviates.
```

Note

Objects generated with hyp, NIG, VG and student.t have to use Xghyp as well. E.g. dNIG(0, NIG()) does not work but dghyp(0, NIG()).

When the skewness becomes very large the functions using qghyp may fail. The functions qqghyp, pairs and portfolio.optimize are based on qghyp.

rghyp(n = 10, multivariate.ghyp)</pre>
```

ghyp-get

Get methods for objects inheriting from class ghyp

Description

These functions simply return data stored within generalized hyperbolic distribution objects, i.e. slots of the classes ghyp and mle.ghyp.ghyp.fit.info extracts information about the fitting procedure from objects of class mle.ghyp.ghyp.data returns the data slot of a gyhp object.ghyp.dim returns the dimension of a gyhp object.ghyp.name returns the name of the distribution of a gyhp object.

Usage

```
ghyp.fit.info(object)
ghyp.data(object)
ghyp.name(object, abbr = FALSE, skew.attr = TRUE)
ghyp.dim(object)
```

Arguments

object An object inheriting from class ghyp.

abbr If TRUE the abbreviation of the ghyp distribution will be returned.

skew.attr If TRUE an attribute will be added to the name of the ghyp distribution stating

whether the distribution is symmetric or not.

Value

ghyp.fit.info returns list with components:

```
logLikelihood
                       The maximized log-likelihood value.
                       The Akaike information criterion.
                 aic
     fitted.params
                       A boolean vector stating which parameters were fitted.
                      A boolean whether optim converged or not.
          converged
             n.iter
                       The number of iterations.
                       Error code from optim.
         error.code
                       Error message from optim.
     error.message
parameter.variance Parameter variance (only for univariate fits).
         trace.pars
                       Trace values of the parameters during the fitting procedure.
```

ghyp-get 21

ghyp.data returns NULL if no data is stored within the object, a vector if it is an univariate generalized hyperbolic distribution and matrix if it is an multivariate generalized hyperbolic distribution.

ghyp.name returns the name of the ghyp distribution which can be the name of a special case. Depending on the arguments abbr and skew.attr one of the following is returned.

abbr == FALSE & skew.attr == TRUE abbr == TRUE & skew.attr == TRUE (A)symmetric Generalized Hyperbolic (A)symm ghyp (A)symmetric Hyperbolic (A)symm hyp (A)symmetric Normal Inverse Gaussian (A)symm NIG (A)symmetric Variance Gamma (A)symm VG (A)symmetric Student-t (A)symm t Gaussian Gauss abbr == FALSE & skew.attr == FALSE abbr == TRUE & skew.attr == FALSE Generalized Hyperbolic ghyp Hyperbolic hyp Normal Inverse Gaussian NIG Variance Gamma VG Student-t t Gaussian Gauss

ghyp. dim returns the dimension of a ghyp object.

Note

ghyp.fit.info requires an object of class mle.ghyp. In the univariate case the parameter variance is returned as well. The parameter variance is defined as the inverse of the negative hesse-matrix computed by optim. Note that this makes sense only in the case that the estimates are asymptotically normal distributed.

The class ghyp contains a data slot. Data can be stored either when an object is initialized or via the fitting routines and the argument save.data.

Examples

ghyp-mle.ghyp-classes Classes ghyp and mle.ghyp

Description

The class "ghyp" basically contains the parameters of a generalized hyperbolic distribution. The class "mle.ghyp" inherits from the class "ghyp". The class "mle.ghyp" adds some additional slots which contain information about the fitting procedure. Namely, these are the number of iterations (n.iter), the log likelihood value (11h), the Akaike Information Criterion (aic), a boolean vector (fitted.params) stating which parameters were fitted, a boolean converged whether the fitting procedure converged or not, an error.code which stores the status of a possible error and the corresponding error.message. In the univariate case the parameter variance is also stored in parameter.variance.

Objects from the Class

Objects should only be created by calls to the constructors ghyp, hyp, NIG, VG, student.t and gauss or by calls to the fitting routines like fit.ghypuv, fit.ghypmv, fit.hypuv, fit.hypmv et cetera.

Slots

Slots of class ghyp:

```
call: The function-call of class call.lambda: Shape parameter of class numeric.alpha.bar: Shape parameter of class numeric.chi: Shape parameter of an alternative parametrization. Object of class numeric.
```

23

psi: Shape parameter of an alternative parametrization. Object of class numeric.

mu: Location parameter of lass numeric.

sigma: Dispersion parameter of class matrix.

gamma: Skewness parameter of class numeric.

model: Model, i.e., (a)symmetric generalized hyperbolic distribution or (a)symmetric special case. Object of class character.

dimension: Dimension of the generalized hyperbolic distribution. Object of class numeric.

expected.value: The expected value of a generalized hyperbolic distribution. Object of class numeric.

variance: The variance of a generalized hyperbolic distribution of class matrix.

data: The data-slot is of class matrix. When an object of class ghypmv is instantiated the user can decide whether data should be stored within the object or not. This is the default and may be useful when fitting eneralized hyperbolic distributions to data and perform further analysis afterwards.

parametrization: Parametrization of the generalized hyperbolic distribution of class character. These are currently either "chi.psi", "alpha.bar" or "alpha.delta".

Slots added by class mle.ghyp:

n.iter: The number of iterations of class numeric.

11h: The log likelihood value of class numeric.

converged: A boolean whether converged or not. Object of class logical.

error.code: An error code of class numeric.

error.message: An error message of class character.

fitted.params: A boolean vector stating which parameters were fitted of class logical.

aic: The value of the Akaike Information Criterion of class numeric.

parameter.variance: The parameter variance is the inverse of the fisher information matrix. This slot is filled only in the case of an univariate fit. This slot is of class matrix.

trace.pars: Contains the parameter value evolution during the fitting procedure. trace.pars of class list.

Extends

Class "mle.ghyp" extends class "ghyp", directly.

Methods

```
A "pairs" method (see pairs).
A "hist" method (see hist).

Examples

ghyp-risk-performance Risk and Performance Measures

Description

Functions to compute the risk measure *Expected Shortfall* and the performance measure *Omega* based on univariate generalized hyperbolic distributions.

ghyp-risk-performance 25

Usage

```
ESghyp(alpha, object = ghyp(), distr = c("return", "loss"), ...)
ghyp.omega(L, object = ghyp(), ...)
```

Arguments

alpha	A vector of confidence levels.
L	A vector of threshold levels.
object	A univarite generalized hyperbolic distribution object inheriting from class ghyp.
distr	Whether the ghyp-object specifies a return or a loss-distribution (see Details).
	Arguments passed from ESghyp to qghyp and from ghyp.omega integrate.

Details

The parameter distr specifies whether the ghyp-object describes a return or a loss-distribution. In case of a return distribution the expected-shortfall on a confidence level α is defined as $\mathrm{ES}_\alpha := \mathrm{E}(X|X \le F_X^{-1}(\alpha))$ while in case of a loss distribution it is defined on a confidence level α as $\mathrm{ES}_\alpha := \mathrm{E}(X|X > F_X^{-1}(\alpha))$.

Omega is defined as the ratio of a European call-option price divided by a put-option price with strike price L (see **References**): $\Omega(L) := \frac{C(L)}{P(L)}$.

Value

ESghyp gives the expected shortfall and ghyp.omega gives the performance measure Omega.

## => the higher the performance, the higher the risk (as it should be)
```

```
ghyp.attribution-class
```

Class ghyp.attribution

Description

The class "ghyp.attribution" contains the Expected Shortfall of the portfolio as well as the contribution of each asset to the total risk and the sensitivity of each Asset. The sensitivity gives an information about the overall risk modification of the portfolio if the weight in a given asset is marginally increased or decreased (1 percent).

The function contribution returns the contribution of the assets to the portfolio expected shortfall.

ghyp.attribution-class 27

Usage

```
contribution(object, ...)
## S4 method for signature 'ghyp.attribution'
contribution(object, percentage = FALSE)
sensitivity(object)
## S4 method for signature 'ghyp.attribution'
sensitivity(object)
## S4 method for signature 'ghyp.attribution'
weights(object)
```

Arguments

object an object inheriting from class ghyp.attribution.

... additional parameters.

percentage boolean. Display figures in percent. (Default=FALSE).

Details

Expected shortfall enjoys homogeneity, sub-additivity, and co-monotonic additivity. Its associated function is continuously differentiable under moderate assumptions on the joint distribution of the assets.

Value

contribution of each asset to portfolio's overall expected shortfall. sensitivity of each asset to portfolio's overall expected shortfall. weights of each asset within portfolio.

Slots

```
ES Portfolio's expected shortfall (ES) for a given confidence level. Class matrix. contribution Contribution of each asset to the overall ES. Class matrix. sensitivity Sensitivity of each asset. Class matrix. weights Weight of each asset.
```

Objects from the Class

Objects should only be created by calls to the constructors ESghyp.attribution.

Note

When showing special cases of the generalized hyperbolic distribution the corresponding fixed parameters are not printed.

summary(portfolio)
## End(Not run)</pre>
```

ghyp.moment

Compute moments of generalized hyperbolic distributions

Description

This function computes moments of arbitrary orders of the univariate generalized hyperbolic distribution. The expectation of $f(X-c)^k$ is calculated. f can be either the absolute value or the identity. c can be either zero or E(X).

Usage

```
ghyp.moment(object, order = 3:4, absolute = FALSE, central = TRUE, ...)
```

Arguments

object	A univarite generalized hyperbolic object inheriting from class ghyp.
order	A vector containing the order of the moments.
absolute	Indicate whether the absolute value is taken or not. If absolute = TRUE then $E(X-c ^k)$ is computed. Otherwise $E((X-c)^k)$. c depends on the argument central. absolute must be TRUE if order is not integer.
central	If TRUE the moment around the expected value $E((X-E(X))^k)$ is computed. Otherwise $E(X^k)$.
	Arguments passed to integrate.

gig-distribution 29

Details

In general ghyp.moment is based on numerical integration. For the special cases of either a "ghyp", "hyp" or "NIG" distribution analytic expressions (see **References**) will be taken if non-absolute and non-centered moments of integer order are requested.

Value

A vector containing the moments.

gig-distribution

The Generalized Inverse Gaussian Distribution

Description

Density, distribution function, quantile function, random generation, expected shortfall and expected value and variance for the generalized inverse gaussian distribution.

Usage

```
dgig(x, lambda = 1, chi = 1, psi = 1, logvalue = FALSE)
pgig(q, lambda = 1, chi = 1, psi = 1, ...)
qgig(p, lambda = 1, chi = 1, psi = 1, method = c("integration", "splines"),
```

30 gig-distribution

```
spline.points = 200, subdivisions = 200,
    root.tol = .Machine$double.eps^0.5,
    rel.tol = root.tol^1.5, abs.tol = rel.tol, ...)

rgig(n = 10, lambda = 1, chi = 1, psi = 1)

ESgig(alpha, lambda = 1, chi = 1, psi = 1, distr = c("return", "loss"), ...)

Egig(lambda, chi, psi, func = c("x", "logx", "1/x", "var"), check.pars = TRUE)
```

Arguments

X	A vector of quantiles.
q	A vector of quantiles.
р	A vector of probabilities.
alpha	A vector of confidence levels.
n	Number of observations.
lambda	A shape and scale and parameter.
chi, psi	Shape and scale parameters. Must be positive.
logvalue	If TRUE the logarithm of the density will be returned.
distr	Whether the ghyp-object specifies a return or a loss-distribution (see Details).
subdivisions	The number of subdivisions passed to integrate when computing the the distribution function pgig.
rel.tol	The relative accuracy requested from integrate.
abs.tol	The absolute accuracy requested from integrate.
method	Determines which method is used when calculating quantiles.
spline.points	The number of support points when computing the quantiles with the method "splines" instead of "integration".
root.tol	The tolerance of uniroot.
func	The transformation function when computing the expected value. x is the expected value (default), $\log x$ returns the expected value of the logarithm of x , $1/x$ returns the expected value of the inverse of x and x returns the variance.
check.pars	If TRUE the parameters are checked first.
	Arguments passed form ESgig to qgig.

Details

qgig computes the quantiles either by using the "integration" method where the root of the distribution function is solved or via "splines" which interpolates the distribution function and solves it with uniroot afterwards. The "integration" method is recommended when few quantiles are required. If more than approximately 20 quantiles are needed to be calculated the "splines" method becomes faster. The accuracy can be controlled with an adequate setting of the parameters rel.tol,

gig-distribution 31

```
abs.tol, root.tol and spline.points.
```

rgig relies on the C function with the same name kindly provided by Ester Pantaleo and Robert B. Gramacy.

Egig with func = "log x" uses grad from the R package *numDeriv*. See the package vignette for details regarding the expectation of GIG random variables.

Value

```
dgig gives the density,
pgig gives the distribution function,
qgig gives the quantile function,
ESgig gives the expected shortfall,
rgig generates random deviates and
Egig gives the expected value of either x, 1/x, log(x) or the variance if func equals var.
```

32 hist-methods

hist-methods	Histogram for univariate generalized hyperbolic distributions	

Description

The function hist computes a histogram of the given data values and the univariate generalized hyperbolic distribution.

Usage

```
## S4 method for signature 'ghyp'
hist(x, data = ghyp.data(x), gaussian = TRUE,
    log.hist = F, ylim = NULL, ghyp.col = 1, ghyp.lwd = 1,
    ghyp.lty = "solid", col = 1, nclass = 30, plot.legend = TRUE,
    location = if (log.hist) "bottom" else "topright", legend.cex = 1, ...)
```

Arguments

X	Usually a fitted univariate generalized hyperbolic distribution of class mle.ghyp. Alternatively an object of class ghyp and a data vector.
data	An object coercible to a vector.
gaussian	If TRUE the probability density of the normal distribution is plotted as a reference.
log.hist	If TRUE the logarithm of the histogramm is plotted.
ylim	The "y" limits of the plot.
ghyp.col	The color of the density of the generalized hyperbolic distribution.
ghyp.lwd	The line width of the density of the generalized hyperbolic distribution.
ghyp.lty	The line type of the density of the generalized hyperbolic distribution.
col	The color of the histogramm.
nclass	A single number giving the number of cells for the histogramm.
plot.legend	If TRUE a legend is drawn.
location	The location of the legend. See legend for possible values.
legend.cex	The character expansion of the legend.
	Arguments passed to plot and qqghyp.

Value

No value is returned.

34 lik.ratio.test

lik.ratio.test Likelihood-ratio test

Description

This function performs a likelihood-ratio test on fitted generalized hyperbolic distribution objects of class mle.ghyp.

Usage

```
lik.ratio.test(x, x.subclass, conf.level = 0.95)
```

Arguments

x An object of class mle.ghyp.

x.subclass An object of class mle.ghyp whose parameters form a subset of those of x.

conf.level Confidence level of the test.

Details

The likelihood-ratio test can be used to check whether a special case of the generalized hyperbolic distribution is the "true" underlying distribution.

The likelihood-ratio is defined as

$$\Lambda = \frac{\sup\{L(\theta|\mathbf{X}) : \theta \in \Theta_0\}}{\sup\{L(\theta|\mathbf{X}) : \theta \in \Theta\}}.$$

Where L denotes the likelihood function with respect to the parameter θ and data \mathbf{X} , and Θ_0 is a subset of the parameter space Θ . The null hypothesis H0 states that $\theta \in \Theta_0$. Under the null hypothesis and under certain regularity conditions it can be shown that $-2\log(\Lambda)$ is asymtotically chi-squared distributed with ν degrees of freedom. ν is the number of free parameters specified by Θ minus the number of free parameters specified by Θ_0 .

The null hypothesis is rejected if $-2\log(\Lambda)$ exceeds the conf.level-quantile of the chi-squared distribution with ν degrees of freedom.

Value

A list with components:

statistic The value of the L-statistic.
p.value The p-value for the test.

df The degrees of freedom for the L-statistic.

H0 A boolean stating whether the null hypothesis is TRUE or FALSE.

logLik-AIC-methods

Extract Log-Likelihood and Akaike's Information Criterion

Description

The functions logLik and AIC extract the Log-Likelihood and the Akaike's Information Criterion from fitted generalized hyperbolic distribution objects. The Akaike information criterion is calculated according to the formula $-2 \cdot \text{log-likelihood} + k \cdot n_{par}$, where n_{par} represents the number of parameters in the fitted model, and k=2 for the usual AIC.

Usage

```
## S4 method for signature 'mle.ghyp'
logLik(object, ...)
## S4 method for signature 'mle.ghyp'
AIC(object, ..., k = 2)
```

Arguments

object An object of class mle.ghyp.
k The "penalty" per parameter to be used; the default k = 2 is the classical AIC.
... An arbitrary number of objects of class mle.ghyp.

Value

Either the Log-Likelihood or the Akaike's Information Criterion.

Note

The Log-Likelihood as well as the Akaike's Information Criterion can be obtained from the function ghyp.fit.info. However, the benefit of logLik and AIC is that these functions allow a call with an arbitrary number of objects and are better known because they are generic.

```

```
mean-vcov-skew-kurt-methods
```

Expected value, variance-covariance, skewness and kurtosis of generalized hyperbolic distributions

Description

The function mean returns the expected value. The function vcov returns the variance in the univariate case and the variance-covariance matrix in the multivariate case. The functions ghyp.skewness and ghyp.kurtosis only work for univariate generalized hyperbolic distributions.

Usage

```
## $4 method for signature 'ghyp'
mean(x)

## $4 method for signature 'ghyp'
vcov(object)

ghyp.skewness(object)

ghyp.kurtosis(object)
```

Arguments

x, object

An object inheriting from class ghyp.

Details

The functions ghyp.skewness and ghyp.kurtosis are based on the function ghyp.moment. Numerical integration will be used in case a Student.t or variance gamma distribution is submitted.

Value

Either the expected value, variance, skewness or kurtosis.

Author(s)

David Luethi

colMeans(vg.sim)
var(vg.sim)
```

pairs-methods

Pairs plot for multivariate generalized hyperbolic distributions

Description

This function is intended to be used as a graphical diagnostic tool for fitted multivariate generalized hyperbolic distributions. An array of graphics is created and qq-plots are drawn into the diagonal part of the graphics array. The upper part of the graphics matrix shows scatter plots whereas the lower part shows 2-dimensional histogramms.

Usage

```
## S4 method for signature 'ghyp'
pairs(x, data = ghyp.data(x), main = "'ghyp' pairwise plot",
    nbins = 30, qq = TRUE, gaussian = TRUE,
    hist.col = c("white", topo.colors(100)),
    spline.points = 150, root.tol = .Machine$double.eps^0.5,
    rel.tol = root.tol, abs.tol = root.tol^1.5, ...)
```

The title of the plot.

Arguments

main

Usually a fitted multivariate generalized hyperbolic distribution of class mle.ghyp.
 Alternatively an object of class ghyp and a data matrix.

 data An object coercible to a matrix.

plot-lines-methods 39

The number of bins of the 2-d histogram. nbins qq If TRUE qq-plots are drawn. If TRUE qq-plots with the normal distribution are plotted. gaussian hist.col A vector of colors of the 2-d histgram. The number of support points when computing the quantiles used by the qq-plot. spline.points Passed to qqghyp. root.tol The tolerance of the quantiles. Passed to uniroot via qqghyp. rel.tol The tolerance of the quantiles. Passed to integrate via qqghyp. The tolerance of the quantiles. Passed to integrate via qqqhyp. abs.tol

```

Arguments passed to plot and axis.

plot-lines-methods

Plot univariate generalized hyperbolic densities

Description

These functions plot probability densities of generalized hyperbolic distribution objects.

Usage

```
## S4 method for signature 'ghyp,missing' plot(x, range = qghyp(c(0.001, 0.999), x), length = 1000, ...) ## S4 method for signature 'ghyp' lines(x, range = qghyp(c(0.001, 0.999), x), length = 1000, ...)
```

Arguments

x range	An univariate ghyp object. The range over which the density will be plotted. The default is the range from the 0.1 % quantile to the 00.0 % quantile. When range has a length greater
	the 0.1 % quantile to the 99.9 % quantile. When range has a length greater than 2 it is assumed to be the vector of quantiles and the density is computed on
	range.
length	The desired length of the density vector.
	Arguments passed to plot and lines respectively.

40 plot.ghyp.attrib

Details

When the density is very skewed, the computation of the quantile may fail. See qghyp for details.

nestle.fit <- fit.tuv(data = smi.stocks[,"Nestle"], symmetric = TRUE)
## Student-t distribution
plot(smi.fit, type = "l", log = "y")
lines(nestle.fit, col = "blue")
## Empirical
lines(density(smi.stocks[,"SMI"]), lty = "dashed")
lines(density(smi.stocks[,"Nestle"]), lty = "dashed", col = "blue")</pre>
```

plot.ghyp.attrib

Plot ES contribution

Description

These functions plot the contribution of each asset to the overall portfolio expected shortfall.

Usage

```
## S3 method for class 'ghyp.attrib'
plot(
    x,
    metrics = c("contribution", "sensitivity"),
    column.index = NULL,
    percentage = FALSE,
    colorset = NULL,
    horiz = FALSE,
    unstacked = TRUE,
    pie.chart = FALSE,
    sub = NULL,
    ...
)
```

plot.ghyp.attrib 41

Arguments

x A ghyp.attribution object.

metrics either the contribution or sensitivity will be plotted.

column.index which column of the object.

percentage plot contribution or sensitivity in percent.

colorset vector of colors for the chart.

horiz plot horizontally.
unstacked unstacked plot.

pie.chart should a pie chart be plotted.

sub subtitle.

... arguments passed to plot function.

## Plot Risk Contribution for each Asset
plot(portfolio.attrib, metrics='contribution')

## End(Not run)</pre>
```

42 portfolio.optimize

portfolio.optimize

Portfolio optimization with respect to alternative risk measures

Description

This function performs a optimization of a portfolio with respect to one of the risk measures "sd", "value.at.risk" or "expected.shortfall". The optimization task is either to find the *global minimum risk* portfolio, the *tangency* portfolio or the *minimum risk* portfolio given a target-return.

Usage

Arguments

object	A multivariate ghyp object representing the loss distribution. In case object gives the return distribution set the argument distr to "return".
risk.measure	How risk shall be measured. Must be one of "sd" (standard deviation), "value.at.risk" or "expected.shortfall".
type	The tpye of the optimization problem. Must be one of "minimum.risk", "tangency" or "target.return" (see Details).
level	The confidence level which shall be used if risk.measure is either "value.at.risk" or "expected.shortfall".
distr	The default distribution is "loss". If object gives the return distribution set distr to "return".
target.return	A numeric scalar specifying the target return if the optimization problem is of type "target.return".
risk.free	A numeric scalar giving the risk free rate in case the optimization problem is of type "tangency".
silent	If TRUE no prompts will appear in the console.
	Arguments passed to optim.

Details

If type is "minimum.risk" the global minimum risk portfolio is returned.

If type is "tangency" the portfolio maximizing the slope of "(expected return - risk free rate) / risk" will be returned.

portfolio.optimize 43

If type is "target.return" the portfolio with expected return target.return which minimizes the risk will be returned.

Note that in case of an elliptical distribution (symmetric generalized hyperbolic distributions) it does not matter which risk measure is used. That is, minimizing the standard deviation results in a portfolio which also minimizes the value-at-risk et cetera.

Value

A list with components:

portfolio.dist An univariate generalized hyperbolic object of class ghyp which represents the

distribution of the optimal portfolio.

risk.measure The risk measure which was used.

risk The risk.

opt.weights The optimal weights.

converged Convergence returned from optim.

message A possible error message returned from optim.

n.iter The number of iterations returned from optim.

Note

In case object denotes a non-elliptical distribution and the risk measure is either "value.at.risk" or "expected.shortfall", then the type "tangency" optimization problem is not supported.

Constraints like avoiding short-selling are not supported yet.

```

qq-ghyp

Quantile-Quantile Plot

Description

This function is intended to be used as a graphical diagnostic tool for fitted univariate generalized hyperbolic distributions. Optionally a qq-plot of the normal distribution can be added.

Usage

```
qqghyp(object, data = ghyp.data(object), gaussian = TRUE, line = TRUE,
    main = "Generalized Hyperbolic Q-Q Plot",
    xlab = "Theoretical Quantiles", ylab = "Sample Quantiles",
    ghyp.pch = 1, gauss.pch = 6, ghyp.lty = "solid",
    gauss.lty = "dashed", ghyp.col = "black", gauss.col = "black",
    plot.legend = TRUE, location = "topleft", legend.cex = 0.8,
    spline.points = 150, root.tol = .Machine$double.eps^0.5,
    rel.tol = root.tol, abs.tol = root.tol^1.5, add = FALSE, ...)
```

qq-ghyp 45

Arguments

object	Usually a fitted univariate generalized hyperbolic distribution of class mle.ghyp. Alternatively an object of class ghyp and a data vector.
data	An object coercible to a vector.
gaussian	If TRUE a qq-plot of the normal distribution is plotted as a reference.
line	If TRUE a line is fitted and drawn.
main	An overall title for the plot.
xlab	A title for the x axis.
ylab	A title for the y axis.
ghyp.pch	A plotting character, i.e., symbol to use for quantiles of the generalized hyperbolic distribution.
gauss.pch	A plotting character, i.e., symbol to use for quantiles of the normal distribution.
ghyp.lty	The line type of the fitted line to the quantiles of the generalized hyperbolic distribution.
gauss.lty	The line type of the fitted line to the quantiles of the normal distribution.
ghyp.col	A color of the quantiles of the generalized hyperbolic distribution.
gauss.col	A color of the quantiles of the normal distribution.
plot.legend	If TRUE a legend is drawn.
location	The location of the legend. See legend for possible values.
legend.cex	The character expansion of the legend.
spline.points	The number of support points when computing the quantiles. Passed to qghyp.
root.tol	The tolerance of the quantiles. Passed to uniroot.
rel.tol	The tolerance of the quantiles. Passed to integrate.
abs.tol	The tolerance of the quantiles. Passed to integrate.
add	If TRUE the points are added to an existing plot window. The legend argument then becomes deactivated.
	Arguments passed to plot.

48 stepAIC.ghyp

stepAIC.ghyp	Perform a model selection based on the AIC	

Description

This function performs a model selection in the scope of the generalized hyperbolic distribution class based on the Akaike information criterion. stepAIC.ghyp can be used for the univariate as well as for the multivariate case.

Usage

Arguments

data A vector, matrix or data. frame.

dist A character vector of distributions from where the best fit will be identified.

symmetric Either NULL, TRUE or FALSE. NULL means that both symmetric and asymmetric models will be fitted. For symmetric models select TRUE and for asymmetric models select FALSE.

... Arguments passed to fit.ghypuv or fit.ghypmv.

Value

A list with components:

best.model The model minimizing the AIC.

all.models All fitted models.

fit.table A data.frame with columns model, symmetric, lambda, alpha.bar, aic, llh (log-Likelihood), converged, n.iter (number of iterations) sorted according to the aic. In the univariate case three additional columns containing the parameters mu, sigma and gamma are added.

transform-extract-methods

Linear transformation and extraction of generalized hyperbolic distributions

Description

The transform function can be used to linearly transform generalized hyperbolic distribution objects (see **Details**). The extraction operator [extracts some margins of a multivariate generalized hyperbolic distribution object.

Usage

```
## S4 method for signature 'ghyp'
transform(`_data`, summand, multiplier)
## S3 method for class 'ghyp'
x[i = c(1, 2)]
```

Arguments

_data An object inheriting from class ghyp.

summand A vector.

multiplier A vector or a matrix.

x A multivariate generalized hyperbolic distribution inheriting from class ghyp.

i Index specifying which dimensions to extract.

Details

If $X \sim GH$, transform gives the distribution object of "multiplier * X + summand", where X is the argument named _data.

If the object is of class mle.ghyp, iformation concerning the fitting procedure (cf. ghyp.fit.info) will be lost as the return value is an object of class ghyp.

Value

An object of class ghyp.
